Package ‘ursa’

March 8, 2022

Type Package
Title Non-Interactive Spatial Tools for Raster Processing and Visualization
Version 3.9.6
Author Nikita Platonov [aut, cre] (<https://orcid.org/0000-0001-7196-7882>)
Maintainer Nikita Platonov <platonov@sevin.ru>
Description S3 classes and methods for manipulation with georeferenced raster data: reading/writing, processing, multi-panel visualization. SWU.
License GPL (>= 2)
URL https://github.com/nplatonov/ursa
BugReports https://github.com/nplatonov/ursa/issues
Depends R (>= 4.1.0)
Imports utils, graphics, grDevices, stats, rgdal, png, jpeg
Suggests proj4, sf (>= 0.6-1), raster, ncdf4, locfit, knitr, rmarkdown, tcltk, sp, methods, fasterize, IRdisplay, caTools, shiny, rgeos, tools, webp, htmlwidgets, htmltools, leaflet, leafem, leafpop, RColorBrewer, ragg, widgetframe, geojsonsf (>= 2.0.0), leaflet.providers, magick

NeedsCompilation yes
ByteCompile no
Repository CRAN

allocate

Rasterization of point data into grid cells

Description

allocate takes x and y coordinates and values from data frame, which is describing point spatial data, and puts them into cells of raster. The certain function (either mean value, sum of values, number of points) is applied for >0 points inside of the exact cell borders.

Usage

allocate(vec, coords = c("x", "y"), nodata = NA, attr = ".+", fun = c("mean", "sum", "n"), cellsize = NA, resetGrid = FALSE, verbose = FALSE)

Arguments

vec data.frame. At least x and y should be in colnames(vec). Is is allowed to use "SpatialPointsDataFrame" from package sp. The "on the fly" reprojection is not supported.

coords Character of length 2. Columns names, which contain coordinates of data points. Raster bands are not produced for specified columns. For misreference of coordinate columns, the attempt to find more appropriate coordinate columns is taken.

fun Character keyword of function, which is applied to value of points, which are dropped into the same cell. Valid values are "mean" (mean value), "sum" (sum of values), "n" (number of points)
nodata Numeric of length 1. This value used to mark NA values in the writing to file.
attr Pattern in the format of regular expressions, which is used to select required columns in data frame. By default (".*") all columns are used.
cellsiz Numeric. Desired size of cell in the raster grid. Used only when source data are not in regular grid. Default is NA; cell size is determined automatically to exclude case of points overlapping.
resetGrid Logical. If TRUE then existing base grid (from session_grid()) will be overwritten. Otherwise using of current grid will be attempted.
verbose Logical. Some output in console. Primarily for debug purposes.

Details
Here fun differs from R-styled fun in such functions as *apply, aggregate.
It was refused “rasterize” for function name to distinguish with rasterize in the package raster

Value
Object of class ursaRaster

Author(s)
Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)
g1 <- session_grid(regrid(session_grid(), mul=1/10))
n <- 1000
x <- with(g1, runif(n, min=minx, max=maxx))
y <- with(g1, runif(n, min=miny, max=maxy))
z <- with(g1, runif(n, min=0, max=10))
da <- data.frame(x=x, y=y, value=z)
res <- c(mean=allocate(da, fun="mean")
   , mean=NA
   , sum=allocate(da, fun="sum")
   , count=allocate(da, fun="n"))
res["mean"] = res["sum"] / res["count"]
print(res)

as.array Export raster object to multidimensional array

Description
In the ursaRaster object the 3-dimensional image data are presented in 2-dimensional matrix. as.array transforms internal 2-dimensional data to the usual 3-dimensional data. as.matrix just extracts image data in internal 2-dimensional format.
Usage

## S3 method for class 'ursaRaster'
as.array(x, ...)

## non-public
.as.array(x, drop = FALSE, flip = FALSE, permute = FALSE, dim = FALSE)

Arguments

... Arguments, which are passed to .as.array.
x ursaRaster object
drop Logical. If drop=TRUE then single-band images are presented without third dimension.
permute Logical. If permute=FALSE then returned array has dimension \((\text{samples, lines, bands})\). If permute=TRUE then returned array has dimension \((\text{lines, samples, bands})\).
flip Logical. If flip=TRUE then vertical flip (reverse coordinates for dimension #2) is applied for output image.
dim Logical. If dim=TRUE then array’s dimension is returned.

Details

Use permute=TRUE to create an object of class raster: as.raster(as.array(...))
The spatial reference system is lost.

Value

If dim=FALSE then as.array returns object of class array.
If dim=TRUE then as.array returns dimension of array.
as.matrix returns object of class matrix.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

as.raster is a function to direct export to the object of class raster.
as.matrix with argument/value coords=TRUE and as.data.frame for object of class ursaRaster keep spatial reference system.

Examples

session_grid(NULL)
a <- pixelsize()
a <- (a-global_min(a))/(global_max(a)-global_min(a))
b <- c(entire=a,half=a/2,double=a*2)
str(m <- as.matrix(b))
### as.data.frame

**Convert raster image to a data frame**

**Description**

as.data.frame reorganizes ursaRaster object into data frame, where first two columns (x and y) are coordinates of cells, and the rest columns are cell values.

**Usage**

```r
## S3 method for class 'ursaRaster'
as.data.frame(x, ...)
```

# non-public
```
.as.data.frame(obj, band = FALSE, id = FALSE, na.rm = TRUE, all.na = FALSE,
col.names = NULL)
```

**Arguments**

- **x, obj**: Object of class ursaRaster
- **...**: Set of arguments, which are recognized via their names (using regular expressions) and classes. Passed to non-public .as.data.frame.

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>band</td>
<td>band</td>
<td>See below.</td>
</tr>
<tr>
<td>id</td>
<td>id</td>
<td>See below.</td>
</tr>
</tbody>
</table>
| na\.
rm         | na.rm          | See below.  |
| all\.
na         | all.na         | See below.  |
| col(\.)\*name(s)\* | col.names     | See below.  |

- **band**: Logical. If band=FALSE then each band is presented by separate column in the data frame. If band=TRUE then band name is presented as a factor in the column $\text{band}$, and values are written in the column $\text{z}$. If band=TRUE then number of rows is
- **id**: Logical. If band=FALSE then is ignored. If id=TRUE then addiditional columns
$id will contain unique cell number in the source raster.

na.rm Logical. If na.rm=FALSE then number of rows for data frame is equal to number of cells of spatial grid of raster. If na.rm=TRUE then cells with 'no data' values for all (all.na=FALSE) or any (all.na=TRUE) bands are omitted.

all.na Logical. If na.rm=FALSE then ignored. If number of rows for data frame is equal to number of cells of spatial grid of raster. If na.rm=TRUE then cells with 'no data' values for all bands are omitted.

col.names Character vector or NULL. Names for columns of data frame. If NULL, then column names are generated from band names. Default is NULL.

Details

The structure of voxel is kept. The number of rows for band=TRUE is equal to the number of rows for band=FALSE multiplied to number of bands. To extract all numeric data with destroying of voxel, you may use followed code:

subset(as.data.frame(obj,band=TRUE),!is.na(z)).

Value

Data frame.

If band=TRUE then

x Horizontal coordinate of cell’s midpoint
y Vertical coordinate of cell’s midpoint
z Value
band Band as a factor
id Optional. Unique number for (x,y) coordinate.

If band=FALSE then

x Horizontal coordinate of cell’s midpoint
y Vertical coordinate of cell’s midpoint
...

Additional columns. Names of columns are names of bands. Values of columns are values of corresponded bands.

If ursaRaster is projected, then data frame has additional attribute attr(...,"proj") with value of PROJ.4 string.

Author(s)

Nikita Platonov <platonov@sevin.ru>
as.integer

Examples

```r
session_grid(NULL)
session_grid(regrid(res=50000, lim=c(-1200000,-1400000,1600000,1800200)))
a0 <- ursa_dummy(nband=3, min=0, max=100)
a0[a0<30 | a0>70] <- NA
names(a0) <- c("x","y","z")
print(a0)
b0 <- as.data.frame(a0)
session_grid(NULL)
a1 <- as.ursa(b0)
print(a1-a0)
session_grid(NULL)
session_grid(regrid(res=5800000))
set.seed(352)
a2 <- as.integer(ursa_dummy(nband=2, min=0, max=100))
a2[a2>50] <- NA
print(a2)
print(b1 <- as.data.frame(a2, na.rm=FALSE))
print(b2 <- as.data.frame(a2, na.rm=TRUE))
print(b3 <- as.data.frame(a2, all.na=TRUE))
print(b4 <- as.data.frame(a2, band=TRUE, na.rm=FALSE))
print(b5 <- as.data.frame(a2, band=TRUE, all.na=FALSE))
print(b6 <- as.data.frame(a2, band=TRUE, all.na=TRUE))
print(b7 <- as.data.frame(a2, band=TRUE, all.na=TRUE, id=TRUE))
```

as.integer

Transform values to type integer

Description

as.integer for object of class ursaRaster truncates decimal part of image values and then converts to type integer.

Usage

```r
## S3 method for class 'ursaRaster'
as.integer(x, ...)
```

Arguments

- `x` ursaRaster object
- `...` Other arguments which passed to function `as.integer` of package base.

Value

Object of class ursaRaster where storage.mode of values is integer.
as.matrix

Convert raster image to a matrix

Description

as.matrix(coords=TRUE) prepares a list from the first band of ursaRaster, which is suitable as input parameter for functions image, contour and filled.contour.

Usage

## S3 method for class 'ursaRaster'
as.matrix(x, ...)

## S3 method for class 'ursaRaster'
x[[i]]

Arguments

x  Object of class ursaRaster

...  Set of arguments, which are recognized via their names (using regular expressions) and classes.

(coord(s)*|crd|^$) Logical If TRUE then list is created with x, y, z components, where component $z$ contains matrix, components $x$ and $y$ are coordinates for elements if matrix.

i  Positive integer or character of length. If integer, then band index. If character, then band name. If missing, then first band (value 1L) is used.

Details

Item colortable is mainly for internal usage, e. g., for mapping. Item proj is useful for conversion back to ursaRaster object by calling as.ursa function.

Extract operator x[[i]] is a wrapper for as.matrix(x[i],coords=TRUE)
as.Raster

Value

Depending of argument coords.

If coords=FALSE, then it is a two-dimensional matrix c(samples\times lines, bands), unclassed from ursaValue class.

If coords=TRUE, then it is a list:

\n\begin{verbatim}
x Numeric. Midpoints of cells on horizontal axis
y Numeric. Midpoints of cells on vertical axis
z Numeric. Matrix of values
attr(*,"proj") PROJ.4 string for grid, defined by x and y
attr(*,"colortable") Optional. Object of class ursaColorTable. Missing if raster has no color table.
\end{verbatim}

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)
a <- ursa_dummy(nband=3,min=0,max=100)
a <- a[a>=20 & a<=80]
ignorevalue(a) <- 121
str(ursa_value(a[2]))
str(as.matrix(a[2]))
b1 <- a[2]
str(b1)
image(b1,asp=1)
b2 <- as.matrix(a[2:3],coords=TRUE)
print(c('theSame?'=identical(b1,b2)))
a2 <- as.ursa(b2)
res <- c(src=a[2],exported_then_imported=a2,diff=a[2]-a2)
print(res)

---

as.Raster Coercion to package 'raster' objects

Description

as.Raster converts singe-band ursaRaster object to raster, multi-band ursaRaster object to brick and list of ursaRaster objects to stack. S4 classes “raster”, “brick”, and “stack” are defined in package raster.
Usage

as.Raster(obj)

## S3 method for class 'ursaRaster'
as.Raster(obj)

## S3 method for class 'list'
as.Raster(obj)

## S3 method for class 'ursaStack'
as.Raster(obj)

## S3 method for class 'NULL'
as.Raster(obj)

Arguments

obj Object of class ursaRaster or list of ursaRaster objects

Details

Package raster is required for conversions.

The uppercase as.Raster is important, because as.raster is used in internal functions for coercion to object of class raster.

Single-banded ursaRaster object (with or without colortable) is coerced to RasterLayer. Colortables are kept.
Multi-banded ursaRaster object is coerced to RasterBrick. Colortables are destroyed.
Multi-layered object (list of ursaRaster objects) is coerced to RasterStack. Colortables are destroyed.

Value

Either RasterLayer, RasterBrick, or RasterStack object.

If package raster is not installed then return value is NULL

Note

Package raster is marked as "Suggested".

Author(s)

Nikita Platonov <platonov@sevin.ru>
Examples

## test is skipped: raster's loading time is close to CRAN allowable test time

```r
session_grid(NULL)
if (requireNamespace("raster")) {
  session_grid(regrid(mul=1/4))
  msk <- ursa_dummy(1,min=0,max=100)>40
  a1 <- ursa_dummy(1,min=200,max=500)[msk]
  a2 <- colorize(a1,ramp=FALSE)
  a3 <- as.integer(ursa_dummy(3,min=0,max=255.99))
  a4 <- ursa_stack(a3[msk])
  if (isLayer <- TRUE) {
    print(a1)
    r1 <- as.Raster(a1)
    message(as.character(class(r1)))
    print(r1)
    print(raster::spplot(r1))
    b1 <- as.ursa(r1)
    print(c(exported=a1,imported=b1,failed=b1-a1))
    print(c(theSameValue=identical(ursa_value(a1),ursa_value(b1))
           ,theSameGrid=identical(ursa_grid(a1),ursa_grid(b1))))
  }
  if (isLayerColortable <- TRUE) {
    r2 <- as.Raster(a2)
    message(as.character(class(r2)))
    print(r2)
    print(raster::spplot(r2))
    b2 <- as.ursa(r2)
    print(c(theSameValue=identical(ursa_value(a2),ursa_value(b2))
           ,theSameGrid=identical(ursa_grid(a2),ursa_grid(b2))))
  }
  if (isBrickOrRGB <- TRUE) {
    r3 <- as.Raster(a3)
    message(as.character(class(r3)))
    print(r3)
    print(raster::spplot(r3))
    raster::plotRGB(r3)
    b3 <- as.ursa(r3)
    print(c(theSameValue=identical(ursa_value(a3),ursa_value(b3))
           ,theSameGrid=identical(ursa_grid(a3),ursa_grid(b3))))
  }
  if (isStack <- TRUE) {
    r4 <- as.Raster(a4)
    message(as.character(class(r4)))
    print(r4)
    print(raster::spplot(r4))
    b4 <- as.ursa(r4)
    print(c(theSameValue=identical(ursa_value(a4),ursa_value(b4))
           ,theSameGrid=identical(ursa_grid(a4),ursa_grid(b4))))
  }
}
```
as.raster

Export raster object to a colored representation.

Description

as.raster transforms object of class ursaRaster to the object of class raster (package grDevices)

Usage

## S3 method for class 'ursaRaster'
as.raster(x, ...)

Arguments

x ursaRaster object

... Set of arguments, which are recognized via their names (using regular expressions) and classes:

max number giving the maximum of the color values range. Passed to function as.raster for S3 class 'array'. Default is 255.

Value

A raster object. It is a matrix. The values of matrix are colors.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

as.array

Examples

session_grid(NULL)
session_grid(regrid(mul=1/2))
a <- ursa_dummy(4,min=0,max=255)
a[a<70] <- NA
compose_open(layout=c(1,4),legend=NULL)
for (i in seq(4)) {
  panel_new()
  panel_plot(as.raster(a[seq(i)]),interpolate=FALSE)
  panel_annotation(paste("Number of channels:" ,i))
}
compose_close()
as.table

op <- par(mfrow=c(2,2),mar=rep(0.5,4))
plot(as.raster(a[1:1]),interpolate=FALSE)
plot(as.raster(a[1:2]),interpolate=FALSE)
plot(as.raster(a[1:3]),interpolate=FALSE)
plot(as.raster(a[1:4]),interpolate=FALSE)
par(op)

as.table Frequency of unique values

Description

as.table is an implementation of function base::table for values of raster image.

Usage

## S3 method for class 'ursaRaster'
as.table(x, ...)

ursa_table(x, ...)

Arguments

x ursaRaster object.
...
Other arguments which passed to function table of package base.

Details

If ursaRaster has a colortable, then values are replaced by names of categories.
ursa_table is synonym to method as.table for class 'ursaRaster'.

Value

Object of class table.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)
a <- colorize(pixelsize(),nbreak=4)
t1 <- as.table(a)
print(t1)
str(t1)
ursa_colortable(a) <- NULL
t2 <- as.table(a)
print(t2)
as.ursa

Create raster image from R objects or GDAL raster files.

Description

as.ursa converts R base objects matrix, array, numeric, data.frame list, sp objects SpatialGridDataFrame, SpatialPixelsDataFrame and SpatialPointsDataFrame, raster objects raster, stack and brick, and GDAL raster files (using functions from rgdal package) to ursaRaster object.

Usage

as.ursa(obj, ...)
as_ursa(obj, ...)

Arguments

obj  R object for coercion
...

Depending on class of obj, arguments are passed to respective functions.

Details

as_ursa is a synonym to as.ursa.

This is a high-level function to create ursaRaster objects. The followed classes of R objects are implemented:

‘Data Class’               ‘Appropriate method’
array                     ursa_new
matrix                    ursa_new
numeric                   ursa_new
data.frame                allocate
SpatialPointsDataFrame (sp) allocate
SpatialPixelsDataFrame (sp) allocate
SpatialGridDataFrame (sp)  ursa_new
list of ursaRaster objects unlist
list returned by sf::gdal_read  ursa_new
list (general)            ursa_new.
ggmap (ggmap)             ursa_new.
raster (raster)           ursa_new.
brick (raster)            ursa_new.
stack (raster)            ursa_new.
bitmap (magick)           ursa_new.
character (GDAL supported file name)  read_gdal.

Generally, allocate is used for objects with non-regular grid, and ursa_new is used for regular grids. The raster grid is defined from object properties or from sessional grid.

Color tables are supported for GDAL file names and raster objects (raster, brick, stack).
For ENVI *.hdr Labelled Raster Files there are alternatives:

1. Read object with GDAL (**read_gdal**);
2. Read object without GDAL (**read_envi**).

**Value**

Object of class ursaRaster

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**Examples**

```r
session_grid(NULL)
a1 <- as.ursa(volcano)
print(a1)
display(a1)

session_grid(NULL)
b <- ursa_dummy(mul=1/16,bandname=format(Sys.Date()+seq(3)-1,"%A"))
print(b)

c1 <- b[[1]] ## equal to 'c1 <- as.matrix(b[1],coords=TRUE)'
str(c1)
b1a <- as.ursa(c1)
print(c(original=b[1],imported=b1a))
print(c(projection.b1a=ursa_proj(b1a)))

session_grid(NULL)
b1b <- as.ursa(c1$z)
print(b1b)
print(c(projection.b1b=ursa_proj(b1b)))

c2 <- as.data.frame(b)
str(c2)

session_grid(NULL)
b2a <- as.ursa(c2)
print(b2a)

session_grid(NULL)
attr(c2,"crs") <- NULL
b2b <- as.ursa(c2)
print(b2b)
print(ursa_grid(b2b))

c3 <- unclass(as.matrix(b,coords=TRUE))
str(c3)

session_grid(b)
b3a <- as.ursa(c3)
print(b3a)
print(ursa_grid(b3a))
```
session_grid(NULL)
b3b <- as.ursa(c3)
print(b3b)
print(ursa_grid(b3b))
c4 <- as.array(b)
str(c4)
session_grid(b)
b4a <- as.ursa(c4)
print(b4a)
print(ursa_grid(b4a))
session_grid(NULL)
b4b <- as.ursa(c4)
print(b4b)
print(ursa_grid(b4b))

n <- 20
c5 <- data.frame(y=runif(n,min=1000000,max=5000000)
               ,x=runif(n,min=-3000000,max=1000000)
               ,value=runif(n,min=0,max=10))
print(head(c5))
session_grid(b)
b5a <- as.ursa(c5)
print(b5a)
display(b5a)
session_grid(NULL)
b5b <- as.ursa(c5)
print(b5b)
display(b5b)

b6 <- as.ursa(system.file("pictures/erdas_spnad83.tif",package="rgdal"))
print(b6)
display(b6,coast=FALSE,col="orange")

## package 'raster' is required -- begin
if (requireNamespace("raster")) {
  r <- raster::brick(system.file("external/rlogo.gri",package="raster"))
  print(r)
b7 <- as.ursa(r)
  ursa_proj(b7) <- ""
p <- ursa_proj(b7)
  print(p)
display_rgb(b7)
}
## package 'raster' is required -- end

---

**bandname**

*Band names for raster image.*

**Description**

`bandname` (names) returns names of bands for object of class `ursaRaster` or existing ENVI labelled `.hdr` file. `bandname<-` (names<-) sets names of bands for object of class `ursaRaster`. 
Usage

bandname(x)
bandname(x) <- value

## S3 method for class 'ursaRaster'
names(x)

## S3 replacement method for class 'ursaRaster'
names(x) <- value

Arguments

x Object of class ursaRaster. In the bandname function it is allowed to specify character `ENVI labelled *.hdr` file name.
value Character of length the same length of number of bands of x

Details

names is a synonym for bandname. names<- is a synonym for bandname<-

Value

For bandname and names, character vector.
For bandname<- and names<-, updated object of class ursaRaster.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

nband

Examples

session_grid(NULL)
a1 <- pixelsize()
a2 <- c("Band 1"=a1,Band2=a1/2,sqrt=sqrt(a1),NA)
print(a2)
print(bandname(a2))
bandname(a2)[1:2] <- c("Original","Half")
print(a2)
print(bandname(a2))
band_group

Extract certain statistics of each band.

Description

Function from this band.* list returns required statistics for each band.

Usage

band_mean(obj)
bond_sd(obj)
bond_sum(obj)
bond_min(obj)
bond_max(obj)
bond_n(obj)
bond_nNA(obj)

Arguments

obj Object of class ursaRaster.

Details

• band_mean returns mean value.
• band_sd returns value of standard deviation with n-1 denominator.
• band_sum returns sum of values.
• band_min returns minimal value.
• band_max returns maximal value.
• band_n returns number of non-NA pixels.
• band_nNA returns number of NA pixels.

Value

Named vector of numerical or integer values. Band names are used for naming.

Note

Currently, implementation is not optimal, because firstly bundle of statistics is computed using band_stat function, and then required statistics is extracted.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

band_stat
Examples

```r
session_grid(NULL)
a <- ursa_dummy()
print(a)
print(a<80)
print(class(a))
a[a<80]
a[a<80] <- NA
b1 <- band_stat(a)
print(b1)
b2.n <- band_n(a)
str(b2.n)
b2.mean <- band_mean(a)
print(b1$mean)
print(b2.mean)
print(b1$mean - b2.mean)
```

---

**band_stat**  
*Computes statistics for each band of raster.*

**Description**

For each band of ursaRaster object, band_stat returns certain statistics (mean, sd, sum, min, max, number of non-NA pixels, number of NA pixels). Regarding to each band, it is *global* operations of map algebra.

**Usage**

```r
band_stat(x, grid = FALSE, raw = FALSE)
```

**Arguments**

- `x` Object of class ursaRaster.
- `grid` Logical. If TRUE then metadata are returned instead of statistics. Default is FALSE.
- `raw` Logical. For the case of raster values are categories, if raw=TRUE, then function returns statistics of categories; if raw=FALSE and names of categories can be transformed to numerical values, then function returns statistics for decategorized values. Default is FALSE.

**Details**

If raster values are not in memory or grid=TRUE then ursa_info is returned.

Generic function print for object of class ursaRaster uses returned value of band_stat function with formatted columns.

Statistics is computed for omitted NA values.
Value

data.frame. Row names are indices of bands. Column names are:

- **name**: Band name.
- **mean**: Mean value.
- **sd**: Value of standard deviation with \( n-1 \) denomination.
- **sum**: Sum of values.
- **min**: Minimal value.
- **max**: Maximal value.
- **n**: Number of non-NA pixels.
- **nNA**: Number of NA pixels.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

Columns extraction from returned data frame is in the group of `band.*` functions.

Examples

```r
session_grid(NULL)
s <- substr(as.character(sessionInfo()),1,48)
a <- reclass(ursa_dummy(mul=1/2,bandname=s),ramp=FALSE)
band_stat(a,grid=TRUE)
b2 <- band_stat(a)
b3 <- band_stat(a,raw=TRUE)
str(b2)
str(b3)
print(b2)
print(a) ## 'print.ursaRaster' uses 'band_stat'
print(a,raw=TRUE)
```

---

**Does any band contain no information?**

Description

Set of functions for checking is any or all bands have no data, and for retrieving indices for non-data bands.

Usage

```r
band_blank(obj, ref = c("any", "0", "NA"), verbose = FALSE)
ursa_blank(obj, ref)
```
Arguments

obj Object of class ursaRaster

ref Character. Definition criteria, what is blank mean. If value "0", then blank is detected, if all values are 0. If value "NA", then blank is detected, if all values are NA. Default value is "NA": both NA and 0 are flags of blank. Non-character values are coerced to character.

verbose Logical. Value TRUE provides progress bar. Default is FALSE.

Details

It is defined locally that if all values of band are NA or 0 (see description to argument ref), then such band is blank. The fact is ursa_new create new object in memory with default values NA, but create_envi writes zeros to disk quick. It is decided to consider both these cases as blank. Function band_blank checks blanks for each band of image. If all bands are blank then function ursa_blank returns TRUE.

Value

Function ursa_blank returns logical value of length 1.

Function band_blank returns logical value of length nband(obj).

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

is.na returns object of class ursaRaster; it is mask of cells, which have NA value.

Examples

session_grid(NULL)
a <- ursa_new(bandname=c("first","second","third","fourth"))
ursa_value(a,"first") <- 0 ## 'a[1] <- 1' works, but it is slow
print(ursa_blank(a))
a[3] <- pixelsize()
print(a)
print(band_blank(a))
print(which(band_blank(a)))
print(ursa_blank(a))
Combine bands into raster brick.

Description

This function is an instrument for appending bands or for reorganizing bands.

Usage

```r
## S3 method for class 'ursaRaster'
c(...)
```

Arguments

`...`  
Objects of class `ursaRaster` or coerced to class `ursaRaster`. First argument should be the object of class `ursaRaster`. The objects in the sequence can be named.

Details

You may use this function to assign new bandname for single-band raster: `objDst <- c('Relative density'=objSrc)`

Use also `Extract` operator `[ ]` to reorganize band sequence.

The returned object can be interpreted as a `brick` in the notation of package `raster`. To produce `stack` just call `list` or `ursa_stack`.

Value

`ursaRaster` object.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

`ursa_brick` converts list of `ursaRaster` objects (`stack`) to a single multiband `ursaRaster` object (`brick`).

Examples

```r
session_grid(NULL)
session_grid(regrid(mul=1/16))
a1 <- ursa_dummy(nband=2)
names(a1) <- weekdays(Sys.Date()+seq(length(a1))-1)
a2 <- ursa_dummy(nband=2)
names(a2) <- names(a1)
print(a1)
```
print(a2)
a3 <- a1[1]
print(names(a3))
a4 <- c(today=a3)
print(names(a4))
print(b1 <- c(a1,a2))
print(b2 <- c(a1=a1))
print(b3 <- c(a1=a1,a2=a2))
print(b5 <- c(a1=a1,a2=a2[1]))
print(b4 <- c(a1,'(tomorrow)'=a1[2]))  ## raster append
print(b6 <- c(a1,50))

---

chunk  

Get indices for partial image reading/writing

Description

In the case of 'Cannot allocate vector of size ...' error message chunk_band returns list of bands indices, which are suitable for allocation in memory at once, chunk_line returns list of lines (rows) indices, which are suitable for allocation in memory at once. chunk_expand is used to expand lines indices and can by applied in focal functions.

Usage

chunk_band(obj, mem = 100, mul = 1)
chunk_line(obj, mem = 100, mul = 1)
chunk_expand(ind, size = 3)

Arguments

obj Object of class ursaRaster
mem Numeric. Memory size in GB, which is suitable for allocation.
mul Numeric. Expansion or reduction factor (multiplier) of default value of memory allocation.
ind Integer. Line indices.
size Integer. Size of focal window.

Value

chunk_band returns list with sequences of bands
chunk_line returns list with sequences of lines
chunk_expand returns list:

src expanded set if line indices
dst matching of source indices in the expanded set
Examples

```r
## 1. Prepare data
session_grid(NULL)
fname <- ursa::.maketmp(2)
a <- create_envi(fname[1], nband=3, ignorevalue=-99)
for (i in seq(nband(a)))
a[i] <- pixelsize()^(1/i)
close(a)
rm(a)

## 2. Read
a <- open_envi(fname[1])
chB <- chunk_band(a,2)
str(chB)
for (i in chB)
  print(a[i])
chL <- chunk_line(a,2.5)
str(chL)
for (j in chL)
  print(a[,j])

## 3. Filtering with partial reading
b <- create_envi(a,fname[2])
fsize <- 15
for (j in chL) {
k <- chunk_expand(j,fsize)
b[,j] <- focal_mean(a[,k$src],size=fsize)[,k$dst]
}
d1 <- b[]

## 4. Filtering in memory
d2 <- focal_mean(a[],size=fsize)
close(a,b)
envi_remove(fname)
print(d1-d2)
print(round(d1-d2,4))
```

Description

`close()` for ursaRaster object closes connection for opened file using inherited function `base::close`. Function `close_envi()` closes opened connection for ENVI binary file.
Usage

## S3 method for class 'ursaRaster'
close(...)

close_envi(...)

Arguments

... Object or sequence of objects of class ursaRaster.

Value

NULL

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

close of base package

Examples

session_grid(NULL)
a <- create_envi()
fname <- a$con$fname
message(paste("Created file",dQuote(basename(fname)),"will be deleted."))
print(dir(pattern=basename(envi_list(fname))))
close(a)
invisible(envi_remove(fname))

codec  Reduce and restore dimensions for sparse data matrix

Description

compress reduces dimension of source image matrix and assigns indices. decompress uses indices for expansion of reduced image matrix.

Usage

decompress(obj)
compress(obj)

Arguments

obj Object of class ursaRaster
Details

After masking, vectorization of lines, points and small polygons image matrix is often sparse. Compressing (compress) is an option to reduce object size in memory. Decompressing (decompress) restore original data matrix.

Value

Object of class ursaRaster

Note

Currently, usage of compressed image matrix is limited. Spatial filtering (e.g. focal_mean) does not operate with compressed data.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
b <- as.data.frame(pixelsize())
b <- subset(b, x>1000000 & x<2000000 & y>3000000 & y<4000000)
a1 <- as.ursa(b)
print(a1)
print(object.size(a1))
a2 <- compress(a1)
print(a2)
print(object.size(a2))
a3 <- decompress(a2)
print(a3)
print(object.size(a3))
print(identical(a1,a3))
```

---

**colorize**

Create color table

Description

colorize assigns color table to raster image.

Usage

colorize(obj, value = NULL, breakvalue = NULL, name = NULL, pal = NULL, inv = NA,
stretch = c("default", "linear", "equal", "mean", "positive",
"negative", "diff", "category", "julian", "date", "time",
"slope", "conc", "sd", "significance", "bathy",
"grayscale", "greyscale", ".onetoone"),)
minvalue = NA, maxvalue = NA, byvalue = NA, ltail = NA, rtail = NA, tail = NA, ncolor = NA, nbreak = NA, interval = 0L, ramp = TRUE, byte = FALSE, lazyload = FALSE, reset = FALSE, origin = "1970-01-01", format = "", alpha = "", colortable = NULL, verbose = FALSE, ...)

Arguments

obj ursaRaster object or one-dimension numeric vector.
value Numeric. Values to be assigned to categories.
breakvalue Numeric. Values to be assigned to intervals.
name Character. Names of categories.
pal Function or character. If function then value should corresponded to function, which creates a vector of colors. If character then values should corresponded to R color names or hexadecimal string of the form "#RRGGBB" or "#RRGGBBAA".
inv Logical. Invert sequence of colors.
stretch Character. Either kind of value transformation ("linear",”equal”) or pre-defined options with palette specification ("positive”,"data","significance”, etc)
minvalue Numeric. Lower range limit.
maxvalue Numeric. Upper range limit.
byvalue Numeric. Increment of the sequence from minvalue to maxvalue.
ltail Numeric. Partition of omitted values at left tail.
rtail Numeric. Partition of omitted values at right tail.
tail Numeric. Partition of omitted values at both tail. If length of tail is 2 then left and right tails may differ.
ncolor Numeric or interer. Number of desired colors (or categories)
nbreak Numeric or interer. Number of desired separators between colors.
interval Integer. How to underwrite categories? Use direct
ramp Logical. Is color ramp required?
byte Logical. Forcing to produce color table for storage in byte format (not more than 255 colors). Default is FALSE.
lazyload Logical. If FALSE then raster is reclassified to categories. If TRUE then color table is created without any change to source raster. Default is FALSE.
reset Logical. If TRUE and source raster has color table, then this color table is destroyed, and new one is created. Default is FALSE.
origin Character. Origin for stretch="date” (passed to function as.Date) and stretch="time” (passed to function as.POSIXct). See description of origin in respective functions. Default is "1970-01-01”.
format Character. Format date/time objects for arguments stretch with values "date”, "time”, or "julian”. Default is "" (character of length 0).
alpha  Character or numeric. The characteristics of transparency. If character, then hexadecimal values between "00" and "FF" are allowed, and then coerced to numeric value between 0 and 255. If numeric, and 0 <= alpha <= 1, then alpha is multiplied to 255. alpha=0 means full transparency, alpha=255 means full opacity. Default is ";" if palette has no alpha channel, then alpha is assign to "FF".

colortable  Object of class ursaColorTable or object of class ursaRaster with color table. Reference color table. Is specified, then all other arguments are ignored, expected lazyload. Default is NULL (unspecified).

verbose  Logical. Some output in console. Primarily for debug purposes.

...  If pal is a function, and argument names are in the format "pal.*" then prefix "pal." is omitted, and the rest part is used for argument names, which are passed to pal function.

Details

colortable is designed to prepare pretty thematic maps.

Color ramping (ramp=TRUE) is not quick in computations and has no effective labelling. It is introduced to visualize non-thematic maps, and it is assumed that labeling can be omitted for such maps.

The labelling implementation is based on some improvements of pretty function. The notation of intervals is mixed by brackets and comparative symbols, for example: "<=1.5", "(1.5,2.5)", "(2.5,3.5)", ">3.5"  

Reserved values for interval:

• 0L or FALSE - no interlavs. Values are interpreted as category, even if they are in non-nominal scale
• 1L or TRUE - each category corresponds to interval. The low limit of lowest category is -Inf. The high limit of highest category is +Inf
• 2L - different implementation of interval=1. In some cases may result more pretty labeling.
  If breaks is numerical vector and colors has zero length, then it is assumed interval scaling, and interval=1L is assigned to unspecified interval
  Finite values of extreme intervals are necessary sometimes, however this option is not implemented currently

Keywords for stretch to create pre-defined color tables:

• "positive" - lower limit is 0. Palette is "Oranges"
• "negative" - higher limit is 0. Palette is "Purples"
• "grayscale","greyscale" - palette is "Greys". Usually used for raw satellite images.
• "mean" - designed for common thematic maps and for averaged map across set of maps. Palette is "Spectral"
• "sd" - designed for spatial mapping of standard deviation across set of maps. Palette is "Yl-GnBu"
• "diff" - diverge palette "RdBu". Absolute values of lower and upper limits are equal, zero is in the middle of palette. Designed for anomaly maps.
colorize

- "slope" - is similar to diff but without extreme colors, which are reserved for contouring of statistically significant areas.
- "significance" - designed to illustrate statistically significant areas of slope. The realization is colorable(obj, value=c(-0.999, -0.99, -0.95, -0.9, -0.5, 0.5, 0.9, 0.95, 0.99, 0.999), interval=1L).
- "category" - Values are interpreted in nominal scale. Palette is based on random colors from "Pairs" palette.
- "conc" - designed for visualization of sea ice concentration data, which have lower limit 0 and higher limit 100. Palette is "Blues".
- "bathy" - designed for ocean depth (bathymetry) maps. Internally colorize(obj, stretch="equal", interval=1L, palname="Blues") is used to detect the crossing from shelf waters to deep water basin. Better practice is to do second step with manual specification of value argument.
- "internal" - continuous colors, designed for conversion to greyscale with keeping of intensities.
- "default" - allowing to detect stretch by intuition, without any strong mathematical criteria.

It is allowed manual correction of labels using followed code example:

```r	names(ursa_colortable(x)) <- c("a<=0", "0<a<=1", "a>1")
```

Value

Object of class ursaRaster with named character vector of item $colortable

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

ursa_colortable, ursa_colortable<-

Examples

```r
session_grid(NULL)
a <- pixelsize()-350
print(a)
b1 <- colorize(a, ramp=FALSE)
print(ursa_colortable(b1))
b2 <- colorize(a, interval=1, stretch="positive", ramp=FALSE)
print(ursa_colortable(b2))
b3 <- colorize(a, interval=2, stretch="positive", ramp=FALSE)
print(ursa_colortable(b3))
b4 <- colorize(a, value=c(150, 250), interval=1)
print(ursa_colortable(b4))
names(ursa_colortable(b4)) <- c("x<=150", "150<x<=250", "x>250")
print(ursa_colortable(b4))
display(b4)
```
Description
Manipulation with color tables of raster images.

Usage

```r
## S3 method for class 'ursaColorTable'
print(x, ...)
## S3 method for class 'ursaColorTable'
x[i]

ursa_colortable(x)
ursa_colortable(x) <- value
ursa_colorindex(ct)
## S3 method for class 'ursaColorTable'
names(x)
## S3 replacement method for class 'ursaColorTable'
names(x) <- value
```

Arguments

- **x** `ursaRaster` object.
- **ct** `ursaColorTable` object with or without indexing.
- **value** Named character vector. In Replacement functions:
  - For `ursa_colortable()`: values are colors in “#RRGGBB” notation or R color names (`colors`). names(value) are names of categories.
  - For names(): values are names of categories. If length of names is n−1, where n is length of colors, then intervaling is assumed, and codevalue are assign to interval breaks.
- **i** Integer vector. Indices specifying elements to extract part (subset) of color table.
- **...** passing to generic `print`. Currently not used.

Details
The example of the class structure
Class 'ursaColorTable' Named chr [1:4] "#313695" "#BCE1EE" "#FDBE70" "#A50026"
  .- attr(*, "names")= chr [1:4] "<= 450" "(450;550]" "(550;650]" "> 650"

It is recommended to use ursa_colortable and ursa_colortable<- instead of colortable and colortable<-. ursa_colortable and colortable are synonyms. ursa_colortable<- and colortable<- are synonyms too. Package raster contains colortable and colortable<- functions. colortable and colortable<- will be remove from this package if the case of frequent joint use of both packages.

If color tables describe continuous and non-intersecting intervals, then print gives additional line of extracted breaks.

Value

ursa_colortable returns value of $colortable element if ursaRaster object.
ursa_colortable<- returns ursaRaster object with modified $colortable element.

Class of $colortable element is “ursaColorTable”. This is named character vector, where names are categories, and values are “#RRGGBB” or R color names.

Extract function [] for ursaColorTable object returns object of class ursaColorTable.

Extract function names for ursaColorTable object returns character vector (names of categories).

Replace function names<- for ursaColorTable object returns ursaColorTable with changed names of categories.

ursa_colorindex returns index (if presents) for ursaColorTable object.

Color tables are written to ENVI header file.

Warning

If colors are specified as R color names, then slow down may appear.

names(ursa_colortable(b2))[4] <- "Polar"
print(ursa_colortable(b2))
display(b2)

commonGeneric

Some generic functions for ursaRaster class.

Description

Set of generic functions, implemented for objects of ursaRaster class.

Usage

## S3 method for class 'ursaRaster'
duplicated(x, incomparables = FALSE, MARGIN = 2, fromLast = FALSE, ...)

## S3 method for class 'ursaRaster'
diff(x, lag = 1, differences = 1, ...)

Arguments

x Object of ursaRaster class
incomparables Passed to S3 method duplicated for class matrix.
MARGIN Overwritten to value 2. Passed to S3 method duplicated for class matrix.
fromLast Passed to S3 method duplicated for class matrix.
lag Passed to default S3 method diff.
differences Passed to default S3 method diff.
... Other arguments, which are passed to the respective S3 method.

Value

duplicated(): logical of length equal to number of bands.
diff(): ursaRaster object.

Author(s)

Nikita Platonov <platonov@sevin.ru>
See Also
duplicated, diff.

Examples

```r
a <- ursa_dummy(5)
a
duplicated(a)
diff(a)
```

---

**compose_close**  
*Finish plotting*

Description

Function `compose_close` does followed tasks: 1) completes all unfinished actions before shutting down graphical device, 2) cuts extra margins, and 3) opens resulted PNG file in the associated viewer.

Usage

```r
compose_close(...)  
## non-public  
.compose_close(kind = c("crop2", "crop", "nocrop"),  
    border = 5, bpp = 0, execute = TRUE, verbose = FALSE)
```

Arguments

Set of arguments, which are recognized via their names and classes, and then passed to `.compose_close`:

<table>
<thead>
<tr>
<th>Pattern (compose_close)</th>
<th>Argument (.compose_close)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(*$</td>

</tbody>
</table>

- **kind**: Character keyword for cutting of excess white spaces. If `kind="nocrop"` then there is no cut. If `kind="crop"` then only outer margins are cutted. If `kind="crop2"` then all outer margins and inner white spaces (e.g., between color bar panel and text caption) are cutted.

- **border**: Non-negative integer. Number of pixels for margins, which are not cropped. Default is 5L.
compose_close

bpp: Integer. Bits per pixel for output PNG file. Valid values are 0L, 8L, 24L. If bpp=0L, then 8 bpp is used for "windows" type of PNG device, and 24 bpp is used for "cairo" type of PNG device. The type of device is specified in compose_open function.

execute: Logical. Should created PNG file be opened in the associated external program for viewing graphical files? Default is TRUE.

verbose: Logical. Value TRUE provides some additional information on console. Default is FALSE.

Details

The cut manipulations (crop="crop" or crop="crop2") are implemented using readPNG and writePNG functions of package png. These functions have limitations in the memory allocation.

Function compose_close clears all internal graphical options, specified during compose_open executing.

Some parameters are specified in compose_open: weather output PNG file will be removed after opening (logical delafter), or what is the time of waiting for file opening and next removing (numerical wait in seconds).

Value

Function returns NULL value.

Warning

Currently, execute=TRUE is implemented for Windows platform only using construction R CMD open \emph{fileout}.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```
session_grid(NULL)
a <- ursa_dummy(nband=6,min=0,max=255,mul=1/4)

## exam 1
compose_open()
compose_close()

## exam 2
compose_open(a)
compose_close()

## exam 3
compose_open("rgb",fileout="tmp1")
compose_plot(a[1:3])
compose_close(execute=FALSE)
Sys.sleep(1)
a <- dir(pattern="tmp1.png")
```
compose_design

print(a)
file.remove(a)

compose_design

Organize multi-panel layout with images and color bars.

Description

compose_design prepares scheme for layout of images and color bars.

Usage

compose_design(...)

Arguments

... 

Set of arguments, which are recognized via their names and classes:

**obj** Object of class ursaRaster or list of objects of class ursaRaster or **NULL**. Default is **NULL**. Used to detect panel layout and coordinate reference system.

**layout** Integer of length 2 or **NA**. Layout matrix has dimensions c(nr, nc), where nr is number of rows, and nc is number of columns. If layout=NA then layout matrix is recognized internally using number of bands of obj and argument ratio. If layout=NA and obj=NULL then matrix c(1,1) is used.

**byrow** Logical. The order of filling of layout matrix. Default is **TRUE**. If byrow=**TRUE** then matrix is filled by rows (from top row, consequently from left element to right element, then next row). If byrow=**FALSE** then matrix is filled by columns.

**skip** Positive integer of variable length. Default in **NULL** (length is zero). Indices of panels in the layout matrix, which are not used.

**legend** The description of rules how color bars (legends) or panel captions are located in the layout. It is the list of embedded lists of two elements, which describe the color bars position in the layout. Default is **NA**, it means using of internal rules. If legend=**NULL** then no plotting of color bars. If legend is positive integer in the range 1L:4L, then single color bar is used and legend’s side is corresponded to margins of R graphic system.

**side** Positive integer 1L, 2L, 3L, or 4L. Default is **NA**. Simplification of color bar position in the case that single color bar is used. The value is corresponded to margins of R graphic system. The synonym of integer value of legend.

**ratio** Positive numeric. The desired ratio of layout sides (width per height). If layout=NA then the dimensions of layout matrix are defined internally to get the given ratio of layout’s width per height. The default is (16+1)/(9+1) in the assumption of optimal filling on the usual 16:9 screens.
compose_design

fixed Logical. If TRUE then it is assuming that layout will have the same proportions as sessional grid sizes (rows and columns). For this case, argument ratio is reassigned as a desired ratio (width per height) for single panel. Default is FALSE.

Details

Function compose_design extracts and validates required arguments from a list of parameters (three-dots construct) and passes them to internal function .compose_design.

Argument legend is a list or coerced to a list. The length of this list is equal to number of color bars; each item describes certain color bar. This description is a list again with two elements, which describes the position of color bar in relation to main panels of images.

If argument legend is in interval 1L:4L then it is interpreted as argument side in functions axis, mtext. Argument side in function compose_design plays the same role. It is introduced for consistency with R graphic system.

In the one of example below (See Examples section) the layout with dimension of two rows by three columns is considered (layout=c(2,3)). The dimension of resulting layout matrix is c(7,9), where 7=2*2+3, and 9=3*2+3.

```
[1,] 0 0 0 0 0 0 0 0 0
[2,] 0 0 0 0 0 0 0 0 0
[3,] 0 0 1 0 2 0 3 0 0
[4,] 0 0 0 0 0 0 0 0 0
[5,] 0 0 4 0 5 0 6 0 0
[6,] 0 0 0 0 0 0 0 0 0
[7,] 0 0 0 0 0 0 0 0 0
```

The complicated color bar structure is specified via R’s list function:

```
> leg <- list("7"=list(row=1,col=0),"8"=list(2,"left")
+     ,"9"=list("full","right"),"10"=list("top","full")
+     ,"11"=list(99,1:2),"12"=list("bottom",3))

> str(leg)
$ 7 :List of 2
 ..$ row: num 1
 ..$ col: num 0
$ 8 :List of 2
 ..$ : num 2
 ..$ : chr "left"
$ 9 :List of 2
 ..$ : chr "full"
 ..$ : chr "right"
$ 10:List of 2
 ..$ : chr "top"
 ..$ : chr "full"
$ 11:List of 2
 ..$ : num 99
```
Here, six color bars are specified. It is a list of six lists (sub-lists). First item of sub-list is row number, and the second one is column number. Integers can be replaces by character keywords.

For row-position, "top" means 0L (less than first row), "bottom" means large integer value (greater than last row, currently, 99L), "first" means 1L, "last" means number of last row (2L in this example), "full" means whole range from first to last rows (1L:2L in this example). Values "top" and "bottom" are used for horizontal color bars (last three sub-lists), and the rest for vertical color bars (first three sub-lists).

For column-position, "left" means 0L (less then first column), "bottom" means large integer value (greater than last column, currently, 99L), "first" means first column (1L), "last" means last column (3L in this example), "full" means whole range from first to last columns (1L:3L in this example). Values "left" and "right" are used for vertical color bars, and the rest are for horizontal ones.

The resulting layout is a sparse matrix with zero values for each even row and each column. These zeros plays role of white space between panels in the plotted layout. In our example, values 1L:6L are corresponded to six map panels, and values 7L:12L are corresponded to six narrow panels of color bars (legends).
Value

It is a list of class ursaLayout.

- **layout**: Integer matrix with dimension c(2*nr+3, 2*nc+3), where nr and nc are number of rows and columns of the layout matrix. The layout matrix of image panels is surrounded by colorbar panels. The original layout matrix is expanded by adding zero columns and rows. In the new matrix each even column has zero values, and each even row has zero values.

- **image**: Nonnegative integer. Number of panels with images.

- **dim**: Nonnegative integer of length two. Number of rows and number of columns for panel layout.

- **legend**: Nonnegative integer. Number of panels with color bars (legends).

The returned value is passed to function `compose_open` and further is kept in the `options` until calling of `compose_close`.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

`session_grid(NULL)`
compose_legend

Plot colorbars or marginal texts.

Description

compose_legend recognizes color tables and characters among arguments and passes them to suitable functions for plotting on margins outside of panel area.
compose_legend

Usage

compose_legend(...)

Arguments

... If first argument is a list, then either ursaColorTable or character objects are detected in this list. ursaColorTable can be extracted from ursaRaster (if presents). Other objects are coerced to character.

If first argument is ursaColorTable or ursaRaster with color tables, then other arguments are interpreted as color tables. If coercion to color table is impossible, the coercion is to character.

legend_colorbar is called for objects of class ursaColorTable. legend_mtext is called for objects of class ursaColorTable. If first argument is a list, then other arguments are passed to respective function calls.

Details

Named list in the first argument is allowed or named vectors are allowed if first argument is not a list. For legend_colorbar name of object can be used as an argument units.

This function is designed to make plot on moderate level of usage with the followed construction:

compose_open(...)
compose_panel(...)
compose_legend(...)
compose_close(...)

Function compose_panel returns list of color tables of plotted rasters, and followed sequence is available:

ct <- compose_panel(a)
compose_legend(ct) # or, if 'a' has color tables, then 'compose_legend(a)'

Value

NULL

Author(s)

Nikita Platonov <platonov@sevin.ru>

**Examples**

```r
session_grid(NULL)
b <- lapply(as.list(ursa_dummy(2)),colorize)
cd <- compose_design(layout=c(1,2),legend=list(list(1,"left"),list(1,"right"),list("top","full"),list("bottom",1)))

for (i in 1:4) {
  compose_open(cd,dev=i==1)
  ct <- compose_panel(b,decor=FALSE)
  if (i==2)
    compose_legend(ct)
  else if (i==3)
    compose_legend(ct[[1]],"Tomorrow"=b[[2]],
                    top="This is example of legend composition",
                    format(Sys.Date(),"(c) %Y")
  else if (i==4)
    compose_legend(c(ct,"top","bottom"),units=c("left","right"))
  compose_close()
}
```

**Description**

`compose_open` create plot layout and open PNG graphic device.

**Usage**

`compose_open(...)`

**Arguments**

- ...: Set of arguments, which are recognized via their names and classes:
  - mosaic: Layout matrix or reference object to produce layout matrix. It is permitted to do not use name for this argument. Multiple types of argument are allowed: 1) object of class ursaRaster, 2) list of ursaRaster objects (raster stack), 3) object of class ursaLayout from function `compose_design`, 4) character keyword or 5) missing. Default is NA.
  - fileout: Character. Name for created output file. Supported PNG (*.png), JPEG (*.jpg), WEBP (*.webp) and SVG (*.svg) extensions. Missed extension assumes PNG. If absent (""), then temporal file is created and removed in wait seconds after opening in the associated external viewer. Default is absent ("").
  - dpi: Positive integer. Dots (or pixels) per inch (DPI). The nominal resolution of created output (default PNG) file. Default is 96L. The same as res argument in the `png` function.
compose_open

pointsize Positive integer. The pointsize of plotted text as it is applied in the `png` function. Default is NA. If `pointsize=NA` then it is taken value `16L` multiplied to relative DPI (`dpi/96`). In the case of unspecified scale and pointsize the size of text is defined internally.

scale Positive numeric or character. The scale factor applied to dimensions of original raster. Default is NA. If scale is unspecified (scale=NA), then scale is defined internally for intuitively better fitting in HD, FHD displays (single-panelled layout 900x700). If scale is character (e.g., "8000000", "1:8000000") then dimensions of image panels are defined using "one centimeter of map is corresponded to 8000000 centimeres of site" rule.

width Positive numeric or character. The desired width of each panel of multipanel layout. If width is numeric, then units are pixels. If width is character (e.g., "12.5", "12.5 cm", "12.5cm") then units are centimeters in agreement with dpi argument. Default is NA. If width is unspecified (width=NA) then value 900 is used for single panelled layout.

height Positive numeric or character. The desired height of each panel of multipanel layout. If height is numeric, then units are pixels. If height is character (e.g., "9.6", "9.6 cm", "9.6cm") then units are centimeters in agreement with dpi argument. Default is NA. If height is unspecified (height=NA) then value 700 is used for single panelled layout.

colorbar or colorbarwidth Positive numeric. Scale factor to increase (colorbar>1) or decrease (colorbar<1) width (the shortest dimension) of color bars (legends). Default value (NA) means 2.8% of image panel width.

indent or space or offset. Positive numeric. Scale factor to increase (space>1) or decrease (space<1) the white space between image panels and between image and color bar panels. Default value (NA) means 0.8% of image panel width.

box Logical. If TRUE then boundary box is plotted around image panels and color bar panels. It is a transparent rectangle with black border. Default is TRUE.

delafter Logical. If TRUE then created PNG file will be deleted after viewing. Default is FALSE for specified file names and TRUE for unspecified (temporal) file names. It is implemented as file removing after opening in the external PNG viewer.

wait Positive numeric. Seconds between PNG file opening in the associated program and file removing. It make sense only if delafter=TRUE. Default is 1.0 (one second).

device or type Character keyword, either "cairo", "windows" or "CairoPNG" for OS Windows, and either "cairo", "cairo-png", "Xlib" or "quartz" for other OSES. Should be plotting be done using cairographics or Windows GDI? The same as type argument in the `png` function, excepting "CairoPNG", which is handed by Cairo package. Default is "cairo".

antialias Character keyword, either "none" or "default". Defines the effect on fonts. The same as antialias argument in the `png` function. Default is "default".

font or family A length-one character vector. Specifies the font family. The same as family argument in the `png` function. Default is "sans" for device="windows"
compose_open

and "Tahoma" for device="cairo".
bg or background Character. The background color in PNG file. Passed as
argument bg to png function. Default is "white"
retina Positive numeric. Scale coefficient for retina displays. Default is taken
fromgetOption("ursaRetina"); if it missed, then 1.
dev Logical. If TRUE then this developer tool shows created layout without any
the followed plot functions from this package are ignored. Default is FALSE
verbose Logical. Shows additional output information in console. Default is
FALSE.

... Arguments, which can be passed to compose_design function.

Details

Other usage of compose_open(...,dev=TRUE) is

compose_open(...,dev=FALSE)
compose_close()

The reason to use compose_design function before compose_open is to reduce number of argu-
ments in the case of complicated layout matrix and non-standard settings.
compose_open passes arguments to png function.

If character values are specified for arguments width, height or scale, then layout development is
oriented to produce PNG file, which will be used as a paper copy. Character values for width and
height are in centimeters. Character value V or 1:V of scale defines scale 1/V.

The Cairo device (device="cairo") is more quick on MS Windows computers. However Windows
GDI may produce less depth of colors (even 8 BPP) in the case of no font antialiasing. Usage of
Windows GDI (device="windows") is a way to produce illustrations for scientific journals with
strict requirements of minimal line width, font size, etc.
The PNG layout reserves extra margins for captions of color bars. These margins are filled by white
spaces. The cropping of layout applies to created PNG file using read-write functions of package
png. Only white ("white", "#FFFFFF") or transparent ("transparent") colors are recognized as
white spaces. Therefore, specification of bg!="white" or bg!="transparent" breaks PNG image
cropping.

It is noted that Cyrillics is supported on Windows GDI (device="windows") and is not supported
on Cairo (device="cairo") types of PNG device on MS Windows platform.
Argument retina is ignored for leaflet-compatible tiling.

Value

Name of created PNG file.

If dev=TRUE then output on console is layout matrix.
The set of required parameters for plotting are kept until function compose_close call via options.

ursaPngAuto For developers. Indicator of high-level functions for internal use (manual set;
value is TRUE). Or, can be missed.
**compose_open**

<table>

compose_open(cl,dev=TRUE)

## exam #05
cl <- compose_design(p,side=3)
compose_open(cl,dev=FALSE,bg="transparent")
compose_close()

### Description

compose_panel divides the multi-band raster image (brick) or layers of raster images (stack) on the sequence of single-band images and plots each image on the separate panel of layout. Panel plotting is finalized by adding of decoration (gridlines, coastline, annotation, scalebar).

### Usage

compose_panel(..., silent = FALSE)

### Arguments

...  Set of arguments, which are passed to panel_new, panel_raster, panel_coastline, panel_graticule, panel_annotation, panel_scalebar.

silent  Logical. Value TRUE cancels progress bar. Default is FALSE.

### Details

For each panel of layout the sequence of called functions is permanent: panel_new --> panel_raster --> panel_coastline --> panel_graticule --> panel_annotation --> panel_scalebar.

If this order is undesirable, then call these functions in the required sequence.

### Value

NULL

### Author(s)

Nikita Platonov <platonov@sevin.ru>
compose_plot

Plot layout of images and color bars.

Description

compose_plot plots images (raster brick or raster stack) and corresponding color bars according to given rectangular layout.

Usage

compose_plot(...)

Arguments

... Set of arguments, which are passed to compose_panel and compose_legend

Details

Function merges to functions. The first one plots image layout and returns list of color tables. The second one plots legend (colorbars) based on returned color tables. Simplified description is:

ct <- compose_panel(...) compose_legend(ct,...)

These two functions are separated to allow use additional plotting on image panel after primary plot of raster and decorations before panel change or legend plot.

Value

This function returns NULL value.

create_envi Create ENVI or GDAL files on disk

Description

create_envi creates ENVI binary and header files on disk. ENVI binary file is filled by blank (zero) values.
create_gdal is a wrapper for creating new object of class GDALTransientDataset.

Usage

create_gdal(x, ...)
create_envi(x, ...)

Arguments

x Filename, or any reference object to help assign properties of new ENVI file.
Can be missed.

... Use name = value sequence. Properties of new ENVI file are extracted from
keywords in 'name' and data types of 'value'.

Details

`create_envi` and `create_gdal` use parameters of grid (boundary box, cell size, projection) from reference object of class `ursaRaster` in argument `x` or calls `session_grid`. You may specify values of GDAL or ENVI binary file later using `<-`. If `x` is object of class `ursaRaster` then metadata parameters (interleave, data type, ignore value, etc) are inherited.

Keywords:

- **fname** - character. File name for created GDAL or ENVI file.

  For `create_envi only`: If `compress` of connections is not specified then example for “file-out” file name:
  
  - "fileout" - If external 'gzip' is found then "fileout.envigz" is created else "fileout.envi"
  - "fileout.envi" - "fileout.envi" is created without any compression.
  - "fileout." - "fileout" is created without any compression.
  - "fileout.bin" - "fileout.bin" is created without any compression.
  - "fileout.img" - "fileout.img" is created without any compression.
  - "fileout.dat" - "fileout.dat" is created without any compression.

- **driver** - character. For `create_gdal only`. Which GDAL driver is used.

- **layername** - character of length>=1. Layernames (‘Band name’ in ENVI header file)

- **bandname** - character of length>=1. Layernames (‘Band name’ in ENVI header file)

- **name** - character of length>=1. Layernames (‘Band name’ in ENVI header file)

- **nodata** - integer or numeric. Value in GDAL or ENVI binary file, which is interpreted as `NA` in R

- **ignore** - integer or numeric. Value in GDAL or ENVI binary file, which is interpreted as `NA` in R

- **ignorevalue** - integer or numeric. Value in GDAL or ENVI binary file, which is interpreted as `NA` in R

- **bg** - integer or numeric. Value in GDAL or ENVI binary file, which is interpreted as `NA` in R

- **connection** - character. For `create_envi only`. `connections` for ENVI binary file.

Valid values are:

- "gz" - connection is "gzfile"
- "bz" - connection is "bzfile"
- "xz" - connection is "xzfile"
- "file" - connection is "file"

- **interleave** - character. Interleave. Valid values are "bsq", "bil", "bip". For `create_gdal` and `driver="GTiff"` valid values are "bsq" and "bil".

- **datatype** - character or integer (numeric). Data type.

Valid values are:

- 1, "byte", "Byte", "ULInt8" = Byte: 8-bit unsigned integer
- 2, "integer", "Int16" = Integer: 16-bit signed integer
create_envi

- 3, "Int32" = Long: 32-bit signed integer
- 5, "Float64" = Double-precision: 64-bit double-precision floating-point
- 11, "UInt8" = Byte: 8-bit signed integer. **Not in specification.** Only for use with this package.
- 12, "UInt16" = Integer: 16-bit unsigned integer
- 13, "UInt32" = Long: 32-bit unsigned integer

Specification [https://www.l3harrisgeospatial.com/docs/ENVIHeaderFiles.html](https://www.l3harrisgeospatial.com/docs/ENVIHeaderFiles.html) is used.

- `byteorder` - numeric (integer). Byte order.
- `bands` - numeric (integer). Number of bands/layers
- `nband` - numeric (integer). Number of bands/layers
- `nlayer` - numeric (integer). Number of bands/layers
- `layers` - numeric (integer). Number of bands/layers
- `compress` - integer (numeric) or logical. **For create_envi only.** Should ENVI binary file be compressed after closing connection.
- `wkt` - integer (numeric) or logical. Forced adding ‘coordinate system string’ to ENVI header file
- `ext` - character. **For create_envi only.** Extension of ENVI binary file. For extensions not in c("envi","bin","dat","img") list

If file name is unknown, then random file name is used with informing via `message()`.

**Value**

Object of class `ursaRaster` with opened connection of GDAL or ENVI binary file.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**See Also**

`ursa_new` creates object of class `ursaRaster` in memory and allows to assign values at once.

Use `session_grid` to check or specify parameters of grid before calling `create_envi`.

Use `[<-` to assign values to ENVI binary file after calling `create_envi`.

Use `close` (or `close_envi`) to close connections.

**Examples**

```
session_grid(NULL)
a <- create_envi()
fname <- a$con$fname
dir(pattern=basename(envi_list(fname)))
close(a)
invisible(envi_remove(fname))
```
a <- create_envi("exam1", layername=paste("Band", 1:5),
                   ignorevalue=99, datatype="Int16", interleave="bil")
ursa_info(a)
print(a[])
close(a)
invisible(envi_remove("exam1"))

---

cubehelix

Generate "cubehelix" palette.

Description
cubehelix returns set of RGB colours, which are screen display of intensity images

Usage
cubehelix(n, value = numeric(), weak = NA, rich = NA, rotate = NA, hue = NA, gamma = 1,
          dark = NA, light = NA, inv = NA, verbose = NA)

Arguments

  n       Positive integer. Length of returned color vector. If n is missing and length of
          value is positive, then length of value. If missing n and empty value, then
          n=256.

  value   Numeric vector of values, which are associated with a palette. If both positive
          and negative values are in this vector, then divergence color palette is returned.
          Default in numeric of length zero (unspecified).

  weak    Numeric. The angle (in degrees) of the helix for color with light intensity. If
          both rich and weak are specified, the rotate is defined as difference between
          rich and weak. If all weak, rich and rotate are unspecified, then random
          values are used. Default is NA (unspecified).

  rich    Numeric. The angle (in degrees) of the helix for color with dark intensity. If
          both rich and weak are specified, the rotate is defined as difference between
          rich and weak. If all weak, rich and rotate are unspecified, then random
          values are used. Default is NA (unspecified).

  rotate  Numeric. The angle of rotation (in degrees) of the helix over the scale; can be
          negative. If rotate and weak are specified, then rich is defined as sum of weak
          and rotate. If rotate and rich are specified, then weak is defined as difference
          between rotate and weak. If all weak, rich and rotate are unspecified, then
          random values are used. Default is NA (unspecified).

  hue     Non-negative numeric. Saturation of color. hue=0 gives pure greyscale. If
          unspecified, then random value in interval [0.9, 1.5] is used. Default is NA (un-
          specified).

  gamma   Numeric. Power of intensity. Intensity is between dark and light, which
          are normalized to interval [0, 1]. gamma changes normalized intensity to
          intensity^gamma. Default is 1.
dark  Positive numeric in interval between 0 and 255. The intensity of the darkest color in the palette. For light backgrounds default is 63. For dark backgrounds default is 14 (inverse order with light).

light  Positive numeric in interval between 0 and 255. The intensity of the lightest color in the palette. For light backgrounds default is 241, for dark backgrounds default is 192 (inverse order with dark).

inv  Logical. Inversion of color intensity. If TRUE then color vector is reversed before return. Default is FALSE.

verbose  Logical. Value TRUE provides information about cube helix on console. Default is NA, which is interpreted as FALSE.

Details

This is modified source code of function `cubeHelix()` from package rje under GPL>=2 license.

The palette design is oriented that figures can be printed on white paper. Under this assumption, light color is for small values, and dark color is for big values. In some computer vision and GIS software black background is used, and in this case light color for big values, and dark color of small values looks more naturally. For some thematic maps big values are light, and small values are small (for example, sea ice concentration: open water is blue, close ice is white). RGB and Grayscale remote sensing and photo imagery use light colors for strong signal, and dark colors for weak signal.

Light background is default for figure (specified by argument `background` in function `compose_open`).

The palette divergency can be defined only if `value` is specified. If all values are positive, or all values are negative, then returned palette is not divergent. For divergent palettes the helix sequence is continuous.

If dark and light are unspecified, the color contrast bewteen dark and light drops on reducing number of colors in returned vector.

Value

Vector of RGB color specification.

  b2[i] <- colorize(a[i],pal=cubehelix(11,weak=45*i,rotate=-270),ncolor=11)
  b3[i] <- colorize(a[i]-127,pal=cubehelix)
  hue <- sample(seq(2)-1,1)
  s <- ifelse(hue==0,NA,runif(1,min=91,max=223))
  b4[i] <- colorize(a[i]-127,pal=cubehelix,pal.hue=hue,pal.dark=s,pal.light=s)
}
display(c(b1,b2),layout=c(2,NA),decor=FALSE)
display(c(b3,b4),layout=c(2,NA),decor=FALSE)

---

**dim**

**Dimension of multiband raster image**

Description

Retrieve the dimension of an object of class ursaRaster. The replacement function is dummy; it doesn’t change raster dimension.

Usage

```r
## S3 method for class 'ursaRaster'
dim(x)
## S3 replacement method for class 'ursaRaster'
dim(x) <- value
```

Arguments

- **x**  
  Object of class ursaRaster
- **value**  
  Any. Ignored
**discolor**

*Destroy color table for raster images.*

**Details**

Use extract operator `[]` and combine function `c` to change third (e.g., temporal) dimension of raster.

Use `regrid` function to change grid parameters and to resize/resample raster into new grid.

**Value**

The 'Extract' function `dim` returns named integer vector of length three: 1) number of lines/rows, 2) number of samples/columns, 3) number of bands/channels/layers.

The 'Replacement' function `dim<-` returns `ursaRaster` object without changes.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**Examples**

```r
session_grid(NULL)
session_grid(regrid(mul = 1/16))
a <- ursa_dummy(nband = 3)
ursa_info(a)
print(dim(a))
dim(a) <- c(25, 00, 34)
print(dim(a))
b <- create_envi("tmp1", bandname = letters[1:5], compress = FALSE)
print(dim(b))
close(b)
envi_remove("tmp1")
```

**Description**

If raster’s categories are integer or numeric, then raster values are restored from names of categories. Otherwise only category names are dropped.

**Usage**

```r
discolor(obj, nodata = NA)
```

**Arguments**

- `obj` Object of class `ursaRaster`
- `nodata` Numeric. Flag value for "no-data". If `NA`, then no-data values are missed. Default is `NA`. 
display

Plot raster image(s) in the PNG format.

Description

High-level function to create multi-panel layout of images and to display with decoration (gridlines, coastlines, scalebar, colorbars) in the PNG format. It is an aggregator of low-level functions for typical plotting.

Usage

display(obj, ...)

Arguments

obj       Object of class ursaRaster or list of ursaRaster objects.
...       Passed to either display_brick or display_stack or display_rgb functions and further to hierarchy of plotting functions:
          • compose_open
            – compose_design
          • compose_plot
            – panel_new
            – panel_raster
            – panel_decor
              * panel_graticule
              * panel_coastline
              * panel_scalebar
              * panel_annotation
            – compose_legend
          • compose_close
**Details**

If argument `obj` is missing (e.g. calling `display()` without parameters) then plotting the sessional CRS with blank image.

If argument `obj` is list of ursaRaster objects (or object of class ursaStack) then `display_stack` is called.

If argument `obj` is object of class ursaRaster and has 3 or 4 bands and values in each band are `integer` and in interval between 0 and 255, then `display_rgb` is called.

If argument `obj` is object of class ursaRaster then firstly internal test is applied to detect either image's bands contains homogeneous information (raster brick) or heterogeneous information (raster stack). Then either `display_brick` or `display_stack` is called. This test is rough due to unknown data origin. It is supposed to adjust kind of plotting by means of direct specification of `display_brick` or `display_stack`.

**Value**

Returned value from either `display_brick` or `display_stack` or `display_rgb` functions.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**See Also**

`display_brick, display_stack, display_rgb`

R-styled plotting: `plot, image`

**Examples**

```r
session_grid(NULL)
set.seed(500)
a.brick <- a.stack <- ursa_dummy(nband=3,min=0,max=255,mul=1/16)
a.stack[3] <- sqrt(a.stack[3])
a.rgb <- as.integer(round(a.brick))
print(a.brick)
print(a.stack)
print(a.rgb)
display(a.brick,decor=FALSE)
display(a.stack,decor=FALSE)
display(a.rgb)
```
display_brick

Plot multi-band homogenous raster image in the PNG format.

Description

Raster image is forced to be interpreted as homogenous (having the same units). It implies creating multi-panel layout with multiple colorbars.

Usage

display_brick(obj, ...)
display_homo(obj, ...)

Arguments

obj Object of class ursaRaster or list of ursaRaster objects.

... Passed to hierarchy of plotting functions:

• compose_open
  – compose_design
• compose_plot
  – panel_new
  – panel_raster
  – panel_decor
  * panel_graticule
  * panel_coastline
  * panel_scalebar
  * panel_annotation
  – compose_legend
• compose_close

Details

If argument obj is list of ursaRaster objects (or object of class ursaStack) then obj is coerced to class ursaRaster (‘stack’ is coerced to ‘brick’).

display_homo is a synonym to display_brick. It is introduced to emphasize the plotting of homogenous object.

Value

Function returns NULL value.

Author(s)

Nikita Platonov <platonov@sevin.ru>
display_rgb

See Also
display, display_stack, display_rgb

Examples

session_grid(NULL)
a <- ursa_dummy(nband=3,min=0,max=250)
a[3] <- sqrt(a[1])
a2 <- ursa_stack(a)
print(a2)
display(a2) # likely 'display_stack' will be called
display_brick(a2,stretch="eq",labels=c(-150,-100,0,10,12,20,100,150))

display_rgb

Plot RGB (RGBA) color composition in the PNG format.

Description

Raster images are forced to be interpreted as color composition with 3 (RGB) or 4 (RGBA) channels. Values should be in the range between 0 and 255.

Usage

display_rgb(obj, ...)

Arguments

obj Object of class ursaRaster or list of ursaRaster objects.
... Passed to hierarchy of plotting functions:
  • compose_open
    - compose_design
  • compose_plot
    - panel_new
    - panel_raster
    - panel_decor
      * panel_graticule
      * panel_coastline
      * panel_scalebar
  • compose_close
Details

If argument obj is list of ursaRaster objects (or object of class ursaStack) then obj is coerced to class ursaRaster ('stack' is coerced to 'brick').

Colorbar is not plotted.

By default, the created PNG has 24 bits per pixel. This is equal to parameter bpp=24 (compose_close). It is allow to specify other value, e.g., display_rgb(a, bpp=8).

By default, labels of gridlines are located in bottom and left sides of the panel with raster. This is equal to parameter margin=c(TRUE,TRUE,FALSE,FALSE) (panel_graticule). It is allow to specify other value, e.g., display_rgb(a, margin=T).

Currently, for color compositions the argument useRaster (panel_raster) is introduced to fix possible coordinate mismatch for Cairo-devices, but have never used.

Value

Function returns NULL value.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

display, display_brick, display_stack

Examples

session_grid(NULL)
a <- ursa_dummy(nband=3)
display_rgb(a)

display_stack

Plot multi-band heterogenous raster images in the PNG format.

Description

Raster images are forced to be interpreted as heterogenous (having the different units). It implies creating multi-panel layout with multiple colorbars.

Usage

display_stack(obj, ...)
display_hetero(obj, ...)
display_stack

Arguments

obj Object of class ursaRaster or list of ursaRaster objects. Passed to hierarchy of plotting functions:

• compose_open
  – compose_design
• compose_plot
  – compose_panel
  * panel_new
  * panel_raster
  * panel_decor
    · panel_graticule
    · panel_coastline
    · panel_scalebar
  * panel_annotation
  – compose_legend
  * legend_colorbar
• compose_close

Details

If argument obj is object of class ursaRaster then obj is coerced to list of ursaRaster objects ('brick' is coerced to 'stack').

The plot layout is either two-columns or two-rows. Extent of coordinate grid has a form of rectangle. The layout selection depends on ratio of rectangle’s sides. For single-column design use parameter layout=c(NA,1L). e.g., display_brick(a,layout=c(NA,1)), for single-row design use parameter layout=c(1,NA). The same is for forcing of two-columns (layout=c(NA,2L)) and two-rows layouts (layout=c(2L,NA)). Other layouts are not applicable for multiple colorbars.

display_hetero is a synonym to display_stack. It is introduced to emphasize the plotting of complex object with heterogeneous elements, for example, having different units.

Value

Function returns NULL value.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)

a <- ursa_dummy(nband=3)
display_stack(a)
ENVI File Manipulation

Description

Management of ENVI files similar to functions of OS file manager.

Usage

```r
envi_exists(pattern = ".+", path = ".", all.files = FALSE, full.names = TRUE, recursive = FALSE, ignore.case = TRUE, exact = FALSE)
envi_list(pattern = ".+", path = ".", all.files = FALSE, full.names = recursive, recursive = FALSE, ignore.case = TRUE, exact = FALSE)
envi_remove(pattern = ".+", path = ".", all.files = FALSE, full.names = recursive, recursive = FALSE, ignore.case = TRUE, verbose = FALSE)
envi_copy(src, dst, overwrite = TRUE)
envi_rename(src, dst, overwrite = TRUE)
```

Arguments

- `pattern`: Either filename (like `basename` function) or mask in format of regular expressions or full path name.
- `path`: Either path name (like `dirname` function) or ignored if `pattern` describes full path.
- `all.files`: A logical value. If FALSE, only the names of visible files are returned. If TRUE, all file names will be returned. Similar to `all.files` argument in `list.files` function.
- `full.names`: A logical value. If TRUE, the directory path is prepended to the file names to give a relative file path. If FALSE, the file names (rather than paths) are returned. Similar to `full.names` argument in `list.files` function.
- `recursive`: Logical. Should the listing recurse into directories? Similar to `recursive` argument in `list.files` function.
- `ignore.case`: Logical. Should pattern-matching be case-insensitive? Similar to `ignore.case` argument in `list.files` function.
- `exact`: Logical. Attempt to cancel regular expressions.
- `verbose`: Logical. TRUE provides some additional information on console.
- `src`: Strings of length 1 or more. Name or directory name or path of source ENVI files.
- `dst`: Strings of length 1 or more. Name or directory name path of destination ENVI files. Length is assuming to be equal to length of `src`.
- `overwrite`: Logical. TRUE overwrites destinations ENVI files. FALSE does nothing if destination ENVI file exists.
Details

Functions do not view content of any files. The major identifier of ENVI files in file system is ENVI header (*.hdr) file. Binary file is searching along 1) original *.envi, *.bin, *.img, *.dat extensions, 2) externally packing *.gz, *.bz2, *.xz extensions, or 3) packed by this package *.envigz, *.bingz extensions. Functions envi_copy() and envi_rename() keeps original extension of ENVI binary file; use file.rename to rename ENVI binary file.

Value

envi_exists() returns integer number of found ENVI files.
envi_list() returns character vector of found ENVI files.
envi_remove() returns character vector of deleted ENVI files.
envi_copy() returns 0L.
envi_rename() returns value of file.rename, which is applied to objects in file system.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
w <- setwd(tempdir())
a1 <- create_envi("tmp1.envi")
a2 <- create_envi("tmp2.")
close(a1,a2)
envi_list()
envi_copy("tmp1","tmp3")
envi_copy("tmp2","tmp4")
envi_list()
envi_rename("tmp3","tmp5")
envi_list()
envi_exists("nofilewithsuchname")
envi_exists("tmp[34]")
envi_remove(".+")
envi_list()
setwd(wd)
```

---

Extract  Extract portion of raster images

Description

This operator is used to get single band or subset of bands from multi-band ursaRaster object. Another purpose is get portions of data including data reading from files.
Usage

```r
## S3 method for class 'ursaRaster'
x[i, j, ..., drop = FALSE]
```

Arguments

- **x**  
  ursaRaster object
- **i**  
  Integer or character. If integer, then band index, specifying bands to extract. If character, either list of band names or character string for regular expression to match band index. In the (spatial, temporal) interpretation of ursaRaster object j points to temporal component.
- **j**  
  Integer. Line index, specifying lines to extract.
- **...**  
  Mentioned for consistence with internal generic function .
  Use `regexp=FALSE` for matching by `match`, and `regexp=TRUE` for matching by Perl-compatible regexps case insensitive `grep`. Default is `FALSE`.
- **drop**  
  Not used. For consistence with generic function.

Details

Operator `\sQuote{[} is high-level implementation for data reading. If `x$value item is not applicable, then value of ursaRaster is not in memory. In this case the controlled by i and j portion is read to memory. If both i and j are missing, then `x[] reads all values from file.

`x[,j]` is appropriate for time series analysis and processing in the case bands have relation to temporal observation. Use `regrid` for geographical subset and cropping.

Value

ursaRaster object with extracter bands. Values (`$value item`) are in memory.

Warning

It is not allowed to read simultaneously portion of bands and portion of lines from file, e.g.,

```r
x <- open_envi(fname)
y <- x[2:3,10:20]
close(x)
```

Such brunch is not implemented in code. You use one of the followed tricks:

```r
x <- open_envi(fname)
y <- x[2:3][,20:30]
close(x)
```

or

```r
x <- open_envi(fname)
y <- x[,20:30][2:3]
close(x)
```
focal_extrem

Author(s)
Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
## Prepare
session_grid(regrid(mul=1/8))
a <- pixelsize()
w <- c("Monday","Tuesday","Wednesday","Thursday","Friday","Saturday","Sunday",
      "MondayAgain")
b <- rep(a/mean(a),length(w))*seq(length(w))-1
bandname(b) <- w
nr <- ursa_rows(b)
bottom <- (as.integer(nr/2)):nr
write_envi(b,"tmp1",compress=FALSE,interleave="bil")

## Extract
print(b["Monday",regexp=TRUE])
print(b["Monday",regexp=FALSE])
print(b["s"])
print(b["^s"])  
d1 <- b[6,bottom]
rm(b)

## Read from file
b <- open_envi("tmp1")
print(b[])
print(b[-c(6:8)])
d2 <- b[,bottom][6]  ## don't use b[6,bottom]
close(b)
envi_remove("tmp1")

## Compare
print(d1)
print(d2)
```

---

**focal_extrem**

*Extremal spatial filter for image*

**Description**

For each band and for each cell, depending of specification, function finds either minimal or maximal value inside of square window. Focal operation of map algebra.

**Usage**

```r
focal_extrem(x, kind = c("min", "max"), size = 3, cover = 1e-06,
         fillNA = FALSE, saveMargin = TRUE, verbose = 0L)
```
focal_min(x, size = 3, cover = 1e-06, fillNA = FALSE, saveMargin = TRUE, verbose = 0L)
focal_max(x, size = 3, cover = 1e-06, fillNA = FALSE, saveMargin = TRUE, verbose = 0L)

Arguments

x
Object of class ursaRaster.

kind
Character. What kind of extremum is required. Allowed values "min" or "max".

size
Positive numeric. Odd values (3, 5, 7, ...) are allowed, but if other value is specified, then it expanded to the next odd value not less than original value. Default is 3L.

cover
Numeric. 0<=cover<=1. Quota for NA values in the focal window in relation to the squared size of the focal window. Quota exceeding leads to recording NA value in the cell. Default is cover=1e-6.

fillNA
Logical. If TRUE then only NA values of source image can be changed, and non-NA values of source image are kept without changes. It may provide less reducing of spatial resolution in the task of spatial interpolation. Default is FALSE.

saveMargin
Logical. If TRUE then adaptive window size is used for cells, where original window goes over image boundary. If FALSE then image is expanded to the half size of focal window by NA values and argument cover is applied to this expanded part. Default is TRUE.

verbose
Integer of 0L, 1L, or 2L, or logical, which is coerced to integer. The level of verbosity. Values >0 provide some additional information on console, verbose=1L is less detailed, verbose=2L is more detailed. Default is 0L.

Details

focal_min(x,...) is a wrapper to focal_extrem(x,"min",...)
focal_max(x,...) is a wrapper to focal_extrem(x,"max",...)

Value

Object of class ursaRaster with the same number of bands as in input raster.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

Other focal operations: focal_mean, focal_median.

Examples

session_grid(NULL)
a <- ursa_dummy(nband=2,mul=1/8,elements=32)
a[a<80] <- NA
b.min <- focal_extrem(a,"min",size=4,cover=0.5,verbose=1L)
b.max <- focal_extrem(a,"max",size=4,cover=0.5,verbose=1L)
print(list(src=a,min=b.min,max=b.max,dif=b.max-b.min))
focal_mean

Low-pass spatial filter for image.

Description

Low-pass filtering by a square window in the image processing. Focal operation of map algebra. Weight of pixels is proportional to cell area inside of focal window.

Usage

focal_mean(x, size = 3.0, cover = 1e-06, fillNA = FALSE, saveMargin = TRUE, noNA = TRUE, verbose = 0L)

Arguments

x Object of class ursaRaster.
size Positive numeric. Size of square focal window. Fractional values are allowed. If size is not odd (3, 5, 7, ...), then window size is expanded to the nearest odd value not less than original value, and pixels on border are taken with the weight, which is proportional to the cell area inside of original size. Default size=3.
cover Numeric. 0<=cover<=1. Quota for NA values in the focal window in relation to all values. Values are taken with the weight proportional of cell areas inside of focal window. Quota exceeding leads to recording NA value in the cell. Default is cover=1e-6.
fillNA Logical. If TRUE then only NA values of source image can be changed, and non-NA values of source image are kept without changes. It may provide less reducing of spatial resolution in the task of spatial interpolation. Default is FALSE.
saveMargin Logical. If TRUE then adaptive window size is used for cells, where original window goes over image boundary. If FALSE then image is expanded to the half size of focal window by NA values and argument cover is applied to this expanded part. Default is TRUE.
oNA Logical. If TRUE then NA values are transformed to numerical constant, which is interpreted as "no data" value. Filter without NA values has more performace, and generally filter with pre- and post-transformations of NA values have more performace too. Default is TRUE.
verbose Integer of 0L, 1L, or 2L, or logical, which is coerced to integer. The level of verbosity. Values >0 provide some additional information on console, verbose=1L is less detailed, verbose=2L is more detailed. Default is 0L.

Details

The reference is always central pixel, even if window size is even.
If size=3 then multiplicator is 3^(-2) and elements have equal weights:
If size=2 then multiplicator is $2^{-2}$ and weights of elements are:

\[
\begin{array}{c}
[,1] [,2] [,3] \\
[1,] 0.25 0.50 0.25 \\
[2,] 0.50 1.00 0.50 \\
[3,] 0.25 0.50 0.25 \\
\end{array}
\]

If size=3.4 then multiplicator is $3.4^{-2}$ and weights of elements are:

\[
\begin{array}{c}
[1,] 0.04 0.20 0.20 0.20 0.04 \\
[2,] 0.20 1.00 1.00 1.00 0.20 \\
[3,] 0.20 1.00 1.00 1.00 0.20 \\
[4,] 0.20 1.00 1.00 1.00 0.20 \\
[5,] 0.04 0.20 0.20 0.20 0.04 \\
\end{array}
\]

Value

Object of class ursaRaster with the same number of bands as in input raster.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
a <- ursa_dummy(nband=1,mul=1/8,elements=0)
a[a<80] <- NA
print(a)
b1 <- focal_mean(a,size=6,cover=0.5,saveMargin=FALSE)
b2 <- focal_mean(a,size=6,cover=0.5,saveMargin=TRUE)
b3 <- focal_mean(a,size=6,cover=0.5,saveMargin=TRUE,fillNA=TRUE)
print(b3-a)
display(c(a,b1,b2,b3),blank.angle=c(-45,45),blank.density=20)
```

Description

For each band and for each cell, function finds median value inside of square window. Focal operation of map algebra.
focal_median

Usage

focal_median(x, size = 3, cover = 1e-06, fillNA = FALSE, saveMargin = TRUE, verbose = 0L)

Arguments

x
Object of class ursaRaster.

size
Positive numeric. Odd values (3, 5, 7, . . .) are allowed, but if other value is specified, then it expanded to the next odd value not less than original value. Default is 3L.

cover
Numeric. 0<=cover<=1. Quota for NA values in the focal window in relation to the squared size of the focal window. Quota exceeding leads to recording NA value in the cell. Default is cover=1e-6.

fillNA
Logical. If TRUE then only NA values of source image can be changed, and non-NA values of source image are kept without changes. It may provide less reducing of spatial resolution in the task of spatial interpolation. Default is FALSE.

saveMargin
Logical. If TRUE then adaptive window size is used for cells, where original window goes over image boundary. If FALSE then image is expanded to the half size of focal window by NA values and argument cover is applied to this expanded part. Default is TRUE.

verbose
Integer of 0L, 1L, or 2L, or logical, which is coerced to integer. The level of verbosity. Values >0 provide some additional information on console, verbose=1L is less detailed, verbose=2L is more detailed. Default is 0L.

Value

Object of class ursaRaster with the same number of bands as in input raster.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid=NULL
a <- ursa_dummy(1,mul=1/8,elements=0,bandname="src")
a[a<80] <- NA
bF <- c(fillNA.F=focal_median(a[1],size=5,cover=0.5,fillNA=FALSE))
bT <- c(fillNA.T=focal_median(a[1],size=5,cover=0.5,fillNA=TRUE))
print(c(diff=bT-bF))
d <- c(a,bF,bT)
print(d)
display(d)
focal_special

Custom spatial filtering for image

**Description**

For each band and for each cell, function calculates value using specific matrix of square window. *Focal* operation of map algebra.

**Usage**

```r
focal_special(x, type = c("custom", "gaussian", "laplacian", "osisaf",
"hires", "correl", "LoG", "sobel", "sobelG"),
  fmask = NULL, size = 3, alpha = 0.5, sigma = (size-1)/4,
  cover = 1 - 1e-06, fillNA = FALSE, saveMargin = FALSE, verbose = 0L)
```

**Arguments**

- **x** Object of class ursaRaster.
- **type** Character, which is checked by `match.arg`.
- **fmask** Numeric square matrix. Filter mask. If NULL then `matrix(1,ncol=1)` is used. Default is NULL.
- **size** Numeric. Diameter of circled filter mask. Coerced to the nearest odd value not less than original value.
- **alpha** Numeric. Parameter alpha for "Laplacian", "LoG", "hires", "correl" filters. Ignored for others. Default is 0.5.
- **sigma** Numeric. Parameter sigma for "Gaussian", "LoG" filters. Ignored for others. Default is 0.5.
- **cover** Numeric. 0<=cover<=1. Quota for NA values in the focal window in relation to the squared size of the focal window. Quota exceeding leads to recording NA value in the cell. Default is cover=1-1e-6.
- **fillNA** Logical. If TRUE then only NA values of source image can be changed, and non-NA values of source image are kept without changes. It may provide less reducing of spatial resolution in the task of spatial interpolation. Default is FALSE.
- **saveMargin** Logical. If TRUE then adaptive window size is used for cells, where original window goes over image boundary. If FALSE then image is expanded to the half size of focal window by NA values and argument cover is applied to this expanded part. Default is FALSE.
- **verbose** Integer of 0L, 1L, or 2L, or logical, which is coerced to integer. The level of verbosity. Values >0 provide some additional information on console, verbose=1L is less detailed, verbose=2L is more detailed. Default is 0L.
Details

Developed under impression from Matlab's "fspecial".

- type="custom"
  Filter mask (argument fmask) should be specified manually.

- type="gaussian"
  Gaussian filter. For cascade filtering (sequence of increasing or decreasing window size) \( \sigma = (\text{size}-1)/4 \) produces the same distribution density relative to window size. If \( \sigma \) is high but not Inf then it is low-pass filter with diameter=size of circular focal window.

- type="laplacian"
  Laplacian filter. Only size=3 makes sense. Any size is coerced to size=3.

- type="osisaf"
  Filter for edge detection. Only size=5 makes sense. Any size is coerced to size=5. TODO (pl): reference

  \[
  \begin{array}{cccccc}
  -0.0625 & -0.0625 & -0.0625 & -0.0625 & -0.0625 \\
  -0.0625 & 0.1250 & 0.1250 & 0.1250 & -0.0625 \\
  -0.0625 & 0.1250 & 0.0000 & 0.1250 & -0.0625 \\
  -0.0625 & 0.1250 & 0.1250 & 0.1250 & -0.0625 \\
  -0.0625 & -0.0625 & -0.0625 & -0.0625 & -0.0625 
  \end{array}
  \]

- type="hires"
  Filter for unsharpening. Only size=3 makes sense. Any size is coerced to size=3.

  -alpha alpha-1 -alpha
  alpha-1 alpha+5 alpha-1
  -alpha alpha-1 -alpha

- type="correl"
  Filter for contrast increasing. Only size=3 makes sense. Any size is coerced to size=3.

  \[
  \begin{array}{cccc}
  \alpha^2 & -\alpha*(1+\alpha^2) & \alpha^2 \\
  -\alpha*(1+\alpha^2) & (1+\alpha^2)^2 & -\alpha*(1+\alpha^2) \\
  \alpha^2 & -\alpha*(1+\alpha^2) & \alpha^2 
  \end{array}
  \]

- type="LoG"
  Laplacian of Gaussian. Filter for edge detection. \( \sigma \) is used, \( \alpha \) is ignored.

- type="sobel"
  Two-directional Sobel filtering. Only size=3 makes sense. Any size is coerced to size=3.

- type="sobelG"
  Sobel gradient. Only size=3 makes sense. Any size is coerced to size=3.

Value

Object of class ursaRaster with the same number of bands as in input raster.

Warning

Laplacian of Gaussian filter (type="LoG") is not implemented clearly due to applying continuous-valued formula to discrete matrix.
get_earthdata

Retrive data from Global Imagery Browse Services (GIBS) using API for Developers

description

get_earthdata allows retrieving georeferences optical satellite images of low and moderate spatial resolution (up to 250m per cell) using GIBS API for Developers.

usage

get_earthdata(bbox = NA, res = c("2km", "1km", "500m", "250m"),
    date = NA, product = "", geocode = "",
    expand = 1.05, border = 0, display = FALSE,
    cache = NA, verbose = FALSE)
Arguments

bbox  Numeric of length 4 or character. Spatial extent in the notation (minx, miny, maxx, maxy). Can be in units of meters or degrees. If all absolute values are less than 360, then units are in degrees and projection is EPSG:3857, else units are in meters and projection is EPSG:3413. If bbox=NULL, then function return list of available products. If bbox=NA then boundary box is attempted for taking from session grid. If character, then boundary box is taken from geocoding. Default is region of Vaigach Island.

res  Character or numeric. Parameter, which is responsible for dimension of output raster image. If character, then zoom is selected using keyword list c("2km", "1km", "500m", "250m") for EPSG:3413. If res<10 then it is interpreted as zoom for Web Map Tile Service (WMTS). If res>100 then res is interpreted as preffered image dimension. If res=NA then res=480L.

date Character or "Date" object. Date for image retrieving. Default is Sys.Date()-1L.

product Character of integer. Data product form GIBS. Currently only MODIS-oriented (corrected reflectance) products are available:
1. "MODIS_Aqua_CorrectedReflectance_Bands721"
2. "MODIS_Terra_CorrectedReflectance_Bands721"
3. "MODIS_Aqua_CorrectedReflectance_TrueColor"
4. "MODIS_Terra_CorrectedReflectance_TrueColor"
5. "VIIRS_SNPP_CorrectedReflectance_TrueColor"
6. "Coastlines"

Please check actual list by calling get_earthdata(bbox=NULL). If numeric, then index of item among available products. Regular expressions can be used to simplify value of product, e.g., case-insensitive "aqua 721", "terra truecolor", "suomi", "SNNP".

geocode Character. Keyword for geocode service. Valid values are "google", "nominatim". Default is ""; several services are considered in the case of failure.

expand Numeric. Multiplier for plotting panel zoom in relation to extent of plotting geometry. Ignored if geocoding is not applied. Default is 1.05.

border Integer. Value in pixels of fixed margins around plotting geometry. Ignored if geocoding is not applied. Default is 0L.

display Logical. Value TRUE forces to display image instead of return it. Default is FALSE.

cache Logical. Is cache used? Default is NA, which is interpreted as TRUE for any requested date excepting not late time of today (approximately 17:00 UTC).

verbose Logical. Value TRUE may provide some additional information on console. Default is FALSE.

Details

Argument method="libcurl" is used in function download.file for tile downloading. Please check capabilities("libcurl").

Valid zoom values (e.g., specified via res argument) are 3:6 for EPSG:3413 and 0:8 for EPSG:3587.
Longitude 180 degrees has a seam in EPSG:3857 (e.g., see bbox=c(170,68,-170,73) and bbox=c(-1600000,1308000,-1370000,1570000) for Wrangel Island. If region crosses longitude 180 degrees in EPSG:3857, then the prior day is taken for Western Hemisphere.

Value

If bbox=NULL, then character vector of available products.
If display=FALSE then object of class ursaRaster with RGBA image.
If display=TRUE then returned value of display_brick.

Author(s)

Nikita Platonov <platonov@sevin.ru>

GIBS API for Developers

Examples

```r
session_grid(NULL)
pr <- get_earthdata()
print(pr,quote=FALSE)

## internet connection is required -- begin
a1 <- get_earthdata(bbox=c(2000000,400000,2300000,700000))
display(a1)

## internet connection is required -- end
a2 <- get_earthdata(product=2,date=Sys.Date()-7L,res=7,bbox=c(57.8,69.4,62.3,70.8))
display(a2)
```

---

**glance**

Command line utility for spatial view of raster or vector GIS file.

Description

glance is a parser of command line arguments for non-public function `.glance`, which creates multi-panel plots for each attribute of vector file or for each band of raster file.

Usage

```r
.glance(dsn, layer = ".*", grid = NULL, field = "+", size = NA, expand = 1,
    border = 27, lat0 = NA, lon0 = NA, resetProj = FALSE, resetGrid = FALSE,
```
glance

```r
style = "auto", feature = c("auto", "field", "geometry"), alpha = NA,
basemap.order = c("after", "before"), basemap.alpha = NA,
engine = c("native", "sp", "sf"), geocode = "", place="",
area = c("bounding", "point", "shape"), zoom = NA, gdal_rasterize = FALSE,
silent = FALSE, verbose = FALSE, ...)
```

**Arguments**

- **dsn**
  Character or object of either ursaRaster, Spatial, or sf classes. If character, then data source name (interpretation varies by driver - for some drivers, dsn is a file name, but may also be a folder, or contain the name and access credentials of a database).

- **layer**
  Character or integer. If integer, then layer index. If character, then pattern (regular expressions) to recognize layer by name. Only one layer selection is allowed. If selected more then one layer, the error message contains indices and names of layers. Usually, datasets (e.g., "ESRI Shapefile") have only one layer. Default is ".*"; interpreted as all layers.

- **grid**
  Object of class ursaGrid or NULL. Reference CRS and boundary box for visualization. If NULL, then CRS and boundary box are zoomed to layer. Default is NULL.

- **field**
  Character. Pattern for field (attribute, column,...) selection by name using regular expressions. Multiple selection is allowed. Default is ".+"; all fields.

- **size**
  Integer of length 1 or 2 or character of length 1. Size of plotting panel in pixels. If character, then parsed to integer of length 1 or 2. Length 2 is used only for web cartography. If length 1, then size defines width of panel, and height is defined automatically. If integer, then width of panel for plotting in pixels. Default is NA; for web cartography value of maximal size of static maps, and code640 for other cases.

- **expand**
  Numeric. Multiplier for plotting panel zoom in relation to extent of plotting geometry. Default is 1.0.

- **border**
  Integer. Value in pixels of fixed margins around plotting geometry. Default is 27L.

- **lat0**
  Numeric. Parallel os zero distortion. If NA, then parallel os zero distortion is determined from object geometry. Actual for "+proj=stere" projections. Default is NA.

- **lon0**
  Numeric. Central meridian, which have vertical direction on the plot. If NA, then central meridian is determined from object geometry. Default is NA.

- **resetProj**
  Logical. Value TRUE overwrites projection of vector file. Default is FALSE.

- **resetGrid**
  Logical. If TRUE, then session grid is ignored, and new session grid is assigned from input file. If FALSE, then input file is nested in the session grid.

- **style**
  Character. Either projection class or source of web-cartography for basemap. Specified by a sentence of words separated by spaces.
• Projection class
  Valid values are "stere", "laea", "merc", "longlat". Default is keyword "auto"; use object projection, if this projection differs from projection class "+longlat", otherwise, projection ("stere" or "merc") is determined internally.

• Web cartography.
  – Static map
    Valid values are "google", "openstreetmap", "sputnikmap". Static maps have priority over tile services. however additional word "static" can be specified in the sentence, e.g., "openstreetmap static" or "static google". Additional parameters for request to web-script can be added in the sentence in the form "argument1=value1 [argument2=value2]", e.g., style="google static maptype=terrain language=ru-RU scale=2".
  – Tile service
    Supported tile services can be returned by calling of non-public function ursa:::.tileService() without arguments. Valid values are "mapnik", "cycle", "transport", "mapsurfer", "sputnik", "thunderforest", "carto", "kosmosnimki", etc.

    By default, if data has no data fields (e.g., geometry only), then basemap is drawn in color, else in grayscale. Adding word "color" (or "colour") to the sentence forces to use colored basemap. Adding word "gray" (or "grey", "greyscale", "grayscale") to the sentence forces to use colored basemap.

    The order of words in the sentence is any.

    Keywords "google", "openstreetmap" force to use "Google Static Map" or "OpenStreetMap static map images" for basemap; the resulted projection has class "+proj=merc".

    feature Character. Appearance of visualization. If "field" then data of each field is plotted on separate panel (number of panels is equal to number of columns in attribute table). If "geometry" then each feature is plotted on separate panel (number of panels is equal to number of rows in attribute table). Default is "auto"; if intersects of features are found, then "geometry" is used, else "field".

    basemap.order Character. The order of basemap layer rendering in the case of web-cartography basemap. If "before", then basemap is plotted before object plot. If "after", then basemap is plotted over object.

    basemap.alpha Character. The saturation of basemap in the case of web-cartography basemap. Default is NA; basemap.alpha=0.5 for basemap.order="before" and basemap.alpha=0.35 for basemap.order="after".

    alpha Character. The opacity of plotted object. Default is NA; 0.75 for basemap.order="before" in web-cartography style, 1.00 - in all other cases.

    engine Character keyword. Forcing to vector files processing by functions from package sp (engine="sp") or package sf (engine="sf", if sf is installed). Default is "native"; if dsn is Spatial object or if sf is not installed, then "sp" is used.

    geocode Character. Keyword for geocode service. Valid values are "google", "nominatim". If dsn is character and file dsn not found, then trying to interpret dsn as a request to geocode service. The output is only basemap of web cartography.
Default is ""; several services are considered in the case of failure. If style is not specified, then "Google Static Map" is used for geocode="google", and "OpenStreetMap static map images" for geocode="nominatim".

place Character. Type of geographical object (river, island) in the geocoding request. If geocode service is "nominatim", then place is searched among attributes "class" and "type". Default is ""; any object is acceptable.

area Character. Keyword of spatial class of geocoded object. "bounding" is used for boundary box; "point" is used for point. Default value is extracted by match.arg(area).

zoom Positive integer or character. Zooming if web-cartography is applied for basemap. If integer, then value of zoom for tile services and staticmap. If character, then "0" means zoom by default (defined internally), "+1" means increment on 1 of default zoom, "+2" means zoom increment on 2, "-1" means zoom decrement on 1, "-2" means zoom decrement on 2, etc. Default is NA; zoom is defined internally.

gdal_rasterize Logical. If TRUE and GDAL utilities are in the system search path, then overlay for panels is formed via rasterization of vector file. GDAL utility "gdal_rasterize" is used. Note, that GDAL (system level) is optional for this package. Default is FALSE.

silent Logical. Value TRUE cancels progress bar. Default is FALSE.

verbose Logical. Logical. Value TRUE may provide some additional information on console. Default is FALSE.

... glance: Arguments, which are passed to .glance or to display.
.glance: Arguments, which are passed to static maps API, colorize, display, etc.

Details

Command line usage implies set of arguments using pair: argument name and argument value. and values in the format "[name1]=value1 [name2]=value2". No spaces around = (equal symbol). Argument name can be omitted, symbol = is omitted too. If argument value has spaces, then argument value should be surrounded by double quotes (fname="my test.shp"). If argument value is matched to R function, then such value should be surrounded by single quotes (layer='density').

Command line usage example: Rscript -e ursa::glance() 'final_more_than_032.sqlite' attr="select" resetProj=TRUE expand=1.5

For OS Windows, bat-file can be created for raster and vector file association: Rscript -e ursa::glance() %*

Command line usage implies external software for PNG view session_pngviewer(TRUE).

Value

glance returns integer: 0L - successful, 10L - call without arguments.

Note

Package sf is 'Suggested' for package ursa.

### internet connection is required
glance("Svalbard")
```

**global operator**

Extract certains statistics for whole image

**Description**

Function from this global.\textbf{FUN} list returns required statistics \textit{FUN} for the whole image.

**Usage**

- `global_mean(x, ursa = FALSE, ...)`
- `global_median(x, ursa = FALSE, ...)`
- `global_sd(x, ursa = FALSE, ...)`
- `global_sum(x, ursa = FALSE, ...)`
- `global_min(x, ursa = FALSE, ...)`
global_max(x, ursa = FALSE, ...)
global_n(x, ursa = FALSE, ...)
global_nNA(x, ursa = FALSE, ...)
global_range(x, ursa = FALSE, ...)

Arguments

x Object of class ursaRaster.

ursa Logical. The class of returned value. If FALSE then numeric vector of length one is returned (for global_range vector has length two). If TRUE then returned value is single-band raster image (two-bands image for global_range) with constant value for all cells (blank image). Default is FALSE.

... Arguments in function global.FUN which are passed to function FUN.

Details

For any function global.FUN, if argument na.rm is not in ..., then FUN is called with forced na.rm=TRUE.

global_range[list of arguments] is implemented as c(global_min[list of arguments], global_max[list of arguments]) with the same list of arguments.

Alternative method to get global statistics is function applying directly to the raster value. For example, sd(ursa_value(x,na.rm=TRUE)). This way is also appropriate for missing global functions: for example, var(ursa_value(x,na.rm=TRUE)).

Value

If ursa=FALSE then numeric.
If ursa=TRUE then object of class ursaRaster.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
a <- ursa_dummy(2,min=-40,max=80)
a[a<0] <- NA
print(a)
a.mean <- global_mean(a)
a.sd <- global_sd(a)
a.sum <- global_sum(a)
a.min <- global_min(a)
a.max <- global_max(a)
a.median <- global_median(a)
print(c(mean=a.mean,sd=a.sd,sum=a.sum,min=a.min,max=a.max,median=a.median))
v.max <- max(ursa_value(a),na.rm=TRUE)
print(c('global_max'='a.max','max(ursa_value())'=v.max,dif=a.max-v.max))
r.max <- global_max(a,ursa=TRUE)
print(r.max)
```
b <- c(a,'appended scalar value'=a.max)
print(b)

---

groupGeneric  Group Generic Functions for raster image

Description
These functions implement arithmetical and logical operations, mathematical functions for objects of class ursaRaster as well as group generic functions from package base do similar for S3 class. These are local operations in the raster algebra (map algebra).

Usage

```r
## S3 method for class 'ursaRaster'
Ops(e1, e2 = NULL)

## S3 method for class 'ursaRaster'
Math(x, ...)

## S3 method for class 'ursaRaster'
Complex(z)

## S3 method for class 'ursaRaster'
Summary(..., na.rm = FALSE)
```

Arguments

- **x** ursaRaster object
- **e1** ursaRaster object
- **e2** Numeric of length 1, matrix, array, or ursaRaster object.
- **na.rm** Logical. If na.rm=TRUE then no-data values are omitted.
- **z** Any.
- **...** For group Math - further arguments passed to methods. See description for generic.

For group Summary - set of arguments, which are recognized via their names (using regular expressions), position and classes.

- cov|cvr Position >1. Numeric between 0 and 1. If proportion of bands with no data for given location exceeds cover then output value is NA (no data). Default is 0.5-1e-3.
- w Position >1. Numeric of length number of bands or NULL. Band weights for weighted mean. Default is NULL; all bands have equal weights.
name  Position >1. Character of length 1. Band name for output raster. Default is ""; band name is assigned automatically.

verb(ose)*  Position >1. Logical. verbose=TRUE provides some additional information on console. Default is FALSE.

Details

The groups are 'Summary', 'Ops', 'Math', and 'Complex'. See “Details” section in the S3 Generic Functions help page.

The group 'Complex' is unsupported.

The groups 'Math' and 'Summary' are implemented completely.

The group 'Ops' has some features.

- Logical operators "<", ">", "<=", ">=", "==", "!=" return 'NA' for value FALSE and '1' for value TRUE to organize cells' masking.
- Unary operator "!" is equal to binary operator operators "!=", where the second argument is scalar value 0 (zero).

The operators of groups 'Math' and 'Ops' destroy color tables.

For group 'Summary' the realization of local operators of map algebra is possible via apply function:
apply(ursa_value(obj),1,function(x) {y <- sd(x)+1;y})
or
as.ursa(apply(obj,1:2,function(x) {y <- sd(x)+1;y}))

Value

Operators of groups 'Complex' return stop
Operators of groups 'Math', 'Ops', 'Summary' return object of class ursaRaster

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

Other S3 generic function for local operations of map algebra are mean, median.
Standard deviation (local) and certain local operations can be extracted using local_stat.

Examples

```r
session_grid(NULL)
session_grid(regrid(mul=1/4))
a1 <- ursa_dummy(nband=3,min=-5*pi,max=5*pi)
print(a1)
	ry(print(complex1 <- Re(a1)))
print(math1 <- a2 <- round(a1))
```
head <- function(x, n = 3L, s = 170, ...) {
  if (n > 0) {
    head(x, n = n - 1L, s = s, ...) 
  } else if (n < 0) {
    tail(x, n = -n - 1L, s = s, ...) 
  } else {
    return(x) 
  }
}

print(head(1:10))
Value

Object of class ursaRaster

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
session_grid(regrid(mul=1/8))
a <- ursa_dummy(nband=101)
print(head(a))
print(tail(a))
print(series(a,2))
print(series(a[1:5]))
```

---

**hist**  
*Histogram of raster image*

Description

Two functions for manipulation with histograms. In function `hist` values of ursaRaster objects are passed to generic function `hist`, which allows compute and optionally plot histograms. Other function, `histogram`, plots histogram in the graphical device `png` directly.

Usage

```r
## S3 method for class 'ursaRaster'
hist(x, ...)

ursa_hist(obj, width = 800, height = 600, ...)
histogram(...)
```

Arguments

- **obj, x**: Object of class ursaRaster
- **width**: Positive integer. Width of histogram’s panel.
- **height**: Positive integer. Height of histogram’s panel.
- **...**: Other arguments, which are passed to `colorize` and `compose_open` functions.
Details

histogram is synonym of ursa_hist.
Function hist for ursaRaster object is defined as hist(ursa_value(obj),...).
In the function histogram each bin corresponds to category. The image splitting to categories
is realized via colorize function. The panel of plotting is constucted using artificial coordinate
system without geographical projection. The purpose of compose_open function is prepare layout
for plotting raster images; in the case of histogram, the purpose of this function is prepare layout
for plotting histogram

Value

Function histogram returns 0L.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

colorize is used to define histogram bins.
compose_open prepares panel for histogram plotting.
hist computes and plots histograms.

Examples

session_grid(NULL)
a <- pixelsize()
hist(a)
histogram(a,breaks=21)

identify Get value and coordinates from location

Description

Functions to extract values of raster image from given location, specified by coordinates in raster
projection, by cell position or by geographical coordinates. Additional utils to convert cell position
and planar coordinates mutually.

Usage

value_xy(obj, ...)
value_ll(obj, ...)
value_cr(obj, ...)

coord_xy(obj, ...)

coord_cr(obj, ...)

**Arguments**

obj Object of class ursaRaster.

... the set of arguments, which are recognized via their names (using regular expressions) and classes:

<table>
<thead>
<tr>
<th>Matched pattern</th>
<th>Function</th>
<th>Used name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ind</td>
<td><em>_</em></td>
<td>ind</td>
</tr>
<tr>

<td>y</td>
</tr>
<tr>
<td>^lon</td>
<td>value_ll</td>
<td>lon</td>
</tr>
<tr>
<td>^lat</td>
<td>value_ll</td>
<td>lat</td>
</tr>
</tbody>
</table>

**Details**

value_xy returns values for location, which is specified by planar coordinates (x, y).

value_cr returns values for location, which is specified by cell position (column, row) relative to upper-left corner of image .

value_ll returns values for location, which is specified by longitude and latitude (long, lat).

coord_xy transforms planar coordinates (x, y) to cell position (column, row).

coord_cr transforms cell position (column, row) to planar coordinates (x, y).

It is required to use a couple of coordinate vectors: (x,y), (c,r) or (lon,lat) of the same length. The unary argument is interpreted as index in internal value storage.

Position in column/row coordinates starts from upper-left corner. The cell of upper-level corner has (1, 1) coordinates (in R indices starts from 1L), whereas in some GIS the same corner cell has (0, 0) coordinates.

The column names of returned matrix are character format of index in internal value storage. This index can be specify in any function as argument ind instead of coordinates (planar, geographical, cell position).

**Value**

For value.* numeric matrix of raster values. Band values for specific coordinates are by column. Set of specific coordinates are by row. rownames are band names, and colnames are index in internal value storage.

For coord.* numeric matrix of coordinates with a vector of couple coordinates, one coordinate per one row. rownames are returned coordinates, and colnames are index in internal value storage.
**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**Examples**

```r
session_grid(NULL)
set.seed(352)
a <- as.integer(ursa_dummy(3,min=0,max=999))
ind <- which(ursa_value(a[1])==890)
print(ind)
msk <- a[1]==890
am <- a[msk]
b <- as.data.frame(am)
b$jx <- b$x+runif(nrow(b),min=-1000,max=1000)
b$jy <- b$y+runif(nrow(b),min=-1000,max=1000)
print(b)
cr1 <- coord_xy(a,x=b$jx,y=b$jy)
cr2 <- coord_xy(a,y=b$y,x=b$x)
cr3 <- coord_xy(a,ind=ind)
print(cr1)
print(list('cr1 and cr2'=all.equal(cr1,cr2),
         'cr2 and cr3'=all.equal(cr2,cr3),
         'cr3 and cr1'=all.equal(cr3,cr1)))
xy1 <- coord_cr(a,c=cr1"c",r=cr1"r",)
print(xy1)
print(list('in x'=identical(unname(xy1"x"),b[,"x",drop=TRUE]),
         'in y'=identical(unname(xy1"y"),b[,"y",drop=TRUE])))
val1 <- value_xy(a,x=b$jx,y=b$jy)
val2 <- value_xy(a,x=b$x,y=b$y)
val3 <- value_cr(a,ind=ind)
val4 <- value_cr(a,c=cr1"c",r=cr1"r")
print(val1)
print(list('val1 and val2'=all.equal(val1,val2),
         'val2 and val3'=all.equal(val2,val3),
         'val3 and val4'=all.equal(val3,val4),
         'val4 and val1'=all.equal(val4,val1)))
ps <- pixelsize()
v <- value_ll(ps,lon=180,lon=70)
print(c('True scale'=v/with(ursa_grid(ps),1e-6*resx*resy)))
```

---

**ignorevalue**

*Extract and assign ‘nodata’ value of raster images.*

**Description**

Ignored values (*aka* ‘nodata’) are implemented via NA values, and are optional for raster images in memory. However, to avoid ambiguity for data storage, it is desirable to specify ignored value. “ENVI .hdr Labelled Raster” supports ‘nodata’ by means of “data ignore value” field in the header file.
Usage

ignorevalue(obj)
ursa_nodata(obj)

ignorevalue(obj) <- value
ursa_nodata(obj) <- value

Arguments

obj ursaRaster object.
value Integer of numeric of length one. Ignored ('nodata') value.

Details

ursa_nodata is synonym to ignorevalue for both Extract and Replace methods.
The 'nodata' value of raster image obj is specified in the item obj$con$nodata.
If values of raster image are in memory then replace function ignorevalue<- also changes 'nodata' values to NA values.

Value

Extract function ignorevalue returns value of $con$nodata item of ursaRaster object.
Replace function ignorevalue<- returns ursaRaster with modified $con$nodata item.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)
a <- round(ursa_dummy(nband=1,min=0.500001,max=4.499999))
print(a)
print(as.table(a))
print(ignorevalue(a))
ignorevalue(a) <- NA
print(as.table(a))
print(ignorevalue(a))
ignorevalue(a) <- 4
print(as.table(a))
print(ignorevalue(a))
print(a)
Description

The "Extract" function `is.na` creates mask for each band. In this mask value `1L` corresponds to `NA` value in the source image, and value `NA` corresponds non-missing values in the source image. The "Replacement" function `is.na<-` assigns numerical value for cells with 'no data' value.

Usage

```r
## S3 method for class 'ursaRaster'
is.na(x)
## S3 method for class 'ursaRaster'
is.infinite(x)
## S3 method for class 'ursaRaster'
is.nan(x)
## S3 replacement method for class 'ursaRaster'
is.na(x) <- value
```

Arguments

- `x` Object of class `ursaRaster`
- `value` Numeric.

Details

These functions are corresponded to `local` operators of map algebra.

Value

"Extract" functions `is.na`, `is.infinite`, `is.nan` return object of class `ursaRaster`.  
"Replacement" function `is.na<-` modifies object of class `ursaRaster`.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
session_grid(regrid(mul=1/4))
a <- ursa_dummy(nband=2,min=0,max=100)
print(a)
```
print(is.na(a))
a2 <- ursa_new(nband=2)
print(a2)
print(is.na(a2))
a3 <- a
a3[a3<30 | a3>70] <- NA
print(a3)
print(is.na(a3))
is.na(a3) <- 200
print(a3)

---

**legend_align**

*Align caption position for legend*

**Description**

When multiple panels on the same axis, the different order of values or different units of values may provoke different shifting of values and caption from panels. `legend_align` repairs it by the taking names of classes of the required rasters. The function output is for argument aling of `legend_colorbar`.

**Usage**

`legend_align(obj)`

**Arguments**

- **obj** Object of class `ursaColorTable`, or object of class `ursaRaster`, or list of `ursaColorTable` or `ursaRaster` objects.

**Details**

The function is defined as:

```
c(unlist(sapply(obj,function(x) names(ursa_colortable(x)))))
```

**Value**

Character vector.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**Legend colorbar**

Plot colorbar
Description

Functions draw single color bar outside of maps panels. `legend_colorbar` (without prefix dot) is a wrapper for non-public `.legend_colorbar` (with prefix dot)

Usage

`legend_colorbar(...)`

## non-public

`.legend_colorbar(ct, units = "", labels = NA, align = NULL, shift = 1, cex = 1, adj = NA, las = 1, forceLabel = FALSE, lomar = 0, himar = 0, turn = FALSE, useRaster = NA, trim = 0L, abbrev = 24L, opacity = NA, verbose = FALSE)`

Arguments

... Set of arguments, which are recognized via their names (using regular expressions) and classes. Passed to non-public `.legend_colorbar`, excepting argument `colorbar`:

<table>
<thead>
<tr>
<th>Matched pattern (legend_colorbar)</th>
<th>Argument (.legend_colorbar)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>colorbar</td>
<td>ct</td>
<td>Prefix for indirect use (e.g., in <code>display</code>). Separated by a dot, e.g., <code>colorbar.units=&quot;mbar&quot;</code>.</td>
</tr>
<tr>
<td>(ct)*</td>
<td>units</td>
<td>See below.</td>
</tr>

<tr>
<td>verb(ose)*</td>
<td>ct</td>
<td>ursaRaster object with color table or object of class ursaColorTable. First argument in <code>legend_colorbar</code>; name can be omitted.</td>
</tr>
<tr>
<td>units</td>
<td>Argument of class character or expression with matching name &quot;unit(s)*&quot; in <code>legend_colorbar</code>. Text, which is used as a caption for color bars. If character then caption is displayed in bold. Default is &quot;:&quot;; no caption.</td>
<td></td>
</tr>
<tr>
<td>labels</td>
<td>Argument of class integer or character with matching name &quot;labels&quot; in <code>legend_colorbar</code>. If labels is vector of length 1, then it is number of labels</td>
<td></td>
</tr>
</tbody>
</table>
at the color bar, else vector of specified values. Default is NA: it means 11 labels for numerical values and 31 labels for categorical values, but this number can be reduced for perpendicular orientation to the axes to prevent label overlapping.

align Argument of class numeric with matching name “align” in legend_colorbar. The indent for right alignment of labels. May be useful, if two or more color bars are located on the same side, but with different units and order of values. Can be specified by the string of maximal length or via `legend_align`. Default is NULL: right alignment of each color bar is independent.

shift Argument of class numeric with matching name “shift” in legend_colorbar. Multiplier for manual correction of labels alignment in the case when automatical alignment is poor. Default is 1: no changes. If shift<1 then labels are shifted to the left. If shift>1 then labels are shifted to the right.

cex Argument of class numeric with matching name "cex" in legend_colorbar. A numerical value giving the amount by which labels should be magnified relative to the default. Default is 1.

adj Argument of class numeric with matching name "adj" in legend_colorbar. Adjustment for labels. For labels parallel to the axes, adj=0 means left or bottom alignment, and adj=1 means right or top alignment. Default is NA: for labels parallel to the axes adj=0.5, for labels perpendicular to the axis adj=1 for numeric and adj=0 for character.

las Argument of values 0, 1, 2, 3 with matching name "adj" in legend_colorbar. The correspondence between directions of axis and labels. The same definition as for `par(las=)`. Default is 1L.

forceLabel Argument of class logical with matching name "forceLabel" in legend_colorbar. If TRUE then all labels are plotted regardless their possible overlapping.

lomar Argument of class numeric, non-negative, with matching name "lomar" in legend_colorbar. Relative shifting of the lower (left or bottom) position of colorbar. Default is 0: the lower position is corresponded to the limit of panel(s). Positive value decreases length of colorbar.

himar Argument of class numeric, non-negative, with matching name "himar" in legend_colorbar. Relative shifting of the higher (right or bottom) position of colorbar. Default is 0: the higher position is corresponded to the limit of panel(s). Positive value decreases length of colorbar.

turn Argument of class logical with matching name "turn" in legend_colorbar. Default is FALSE: lower value is on left or bottom, higher value is on right or top. If turn=TRUE, then opposite order.

useRaster Argument of class logical with matching name "useRaster" in legend_colorbar. Passed as argument useRaster to function `image`. Default is NA, which is interpreted as TRUE for "cairo" graphical device and as FALSE for "windows" graphical device (see description of argument type in `png`).

trim Argument of values 0L, 1L, 2L with matching name "trim" in legend_colorbar. Determines behaviour for plotting marginal labels. If 0L, then marginal labels are displayed as is. If 1L, then marginal labels are shifted inside of color bar to prevent their outcrop to the panel(s) limits. If 2L then outtapped labels are not displayed.
abbrev Argument of class integer or logical with matching name “abbrev” in \texttt{legend\_colorbar}. TRUE is interpreted as default value. FALSE is interpreted as 0L. If positive, then labels are abbreviated, and this argument is passed as argument minlength to function \texttt{abbreviate}: \texttt{abbreviate(label,minlength=abbrev,strict=TRUE)}. If abbreviation is failed (e.g., non-ASCII symbols), the \texttt{subset} is applied.

opacity Argument of class integer or logical with matching name “abbrev” in \texttt{legend\_colorbar}. Responses for shading of color bar. If FALSE or 0, then no shading. If TRUE or 1, then shading is forced. Default is NA; if semi-transparence is detected, then shading is applied.

verbose Argument of class logical with matching name "verb(ose)\*' in \texttt{legend\_colorbar}. Value TRUE may provide some additional information on console. Default is FALSE.

Details

If units are expression, then possible way for formatting is:

\begin{verbatim}
units=as.expression(substitute(bold(degree*C)))
\end{verbatim}

Value

\texttt{NULL}

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)
display(ursa_dummy(1), units="Required 99 labels; displayed less"
, colorbar.labels=99, las=3, gridline.trim=FALSE, colorbar.trim=1L)
cname <- c("Apple", "Orange", "Cherry", "Blueberry", "Strawberry", "Currant")
a <- ursa_dummy(4)
b <- list(colorize(a[1], value=seq(50, 200, length=length(cname))
, name=cname#, stretch="category")
, colorize(a[2]*10, ramp=FALSE), colorize(a[3]*100), colorize(a[4]/10))
la <- legend_align(b[3:4])
leg <- vector(”list”, 10)
leg[[1]] <- list(1, “left”)
leg[[2]] <- list(1, “right”)
for (i in seq(4)) {
  leg[[i+2]] <- list(“top”, i)
  leg[[i+6]] <- list(“bottom”, i)
}
compose_open(layout=c(1, 4), legend=leg, scale=NA, dev=FALSE) # use ‘dev=TRUE’ to check layout
compose_panel(b)
legend_colorbar(b[[1]], lomar=20, himar=0) ## “left”
legend_colorbar(b[[4]], labels=c(6, 7.5, 12, 15, 20)
, units="Manual set of labels") ## “right”
legend_colorbar(b[[1]], las=2, adj=0.5, turn=TRUE, lomar=6, himar=6
### legend_mtext

#### Description

Functions write text outside of maps panels. `legend_mtext` (without prefix dot) is a wrapper for non-public `.legend_mtext` (with prefix dot).

#### Usage

```r
legend_mtext(...)  
```

#### Arguments

- `...`: Set of arguments, which are recognized via their names (using regular expressions) and classes. Passed to non-public `.legend_mtext`, excepting argument `mtext`:
  - `mtext`: Prefix for indirect use (e.g., in `compose_legend`). Separated by a dot `"."`, e.g., `mtext.cex=0.85`.

<table>
<thead>
<tr>
<th>Matched pattern (legend_colorbar)</th>
<th>Argument (.legend_colorbar)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text</code></td>
<td><code>text</code></td>
<td>See below.</td>
</tr>
<tr>
<td><code>cex</code></td>
<td><code>cex</code></td>
<td>See below.</td>
</tr>
</tbody>
</table>

- `text`: Argument of class character or expression with matching name "text" (or without name) in `legend_mtext`. Text, which is displayed. If character then text is displayed in bold. Default is "Title/subtitle".
- `cex`: Argument of class numeric with matching name "cex" in `legend_mtext`. A
local_group

numerical value giving the amount by which labels should be magnified relative to the default. Default is 1.

Details

If text is expression, then possible way for formatting is:

    text=as.expression(substitute(bold(italic("Omega powered by alpha is ",Omega^alpha))))

Value

Returned value of function mtext from package graphics.

Author(s)

Nikita Platonov <platonov@sevin.ru>

    compose_legend
    legend_colorbar

Examples

    session_grid(NULL)
    a <- ursa_dummy(1,min=-10,max=+30)
    compose_open(legend=list("right","top","bottom","left"))
    panel_new()
    ct <- panel_raster(a)
    legend_colorbar(ct#,units=as.expression(substitute(bold(degree*C))))
    legend_mtext("Characters are in bold")
    legend_mtext(as.expression(substitute(italic(paste("Units can be interpreted as","degree*C")),cex=0.7))
    legend_mtext(text=as.expression(substitute(italic(paste("Omega powered by alpha is ",~Omega^alpha))))
    compose_close(execute=!FALSE)

local_group

Create single-band raster using statistics of multi-bands raster.

Description

    Local operations (mean value, sum of values, median, minimum, maximum) of map algebra for multi-bands ursaRaster object.
Usage

local_mean(x, cover = 0.5 - 1e-3, weight = NULL, verbose = FALSE, bandname = "mean")
local_sum(x, cover = 0.5 - 1e-3, weight = NULL, verbose = FALSE, bandname = "sum")
local_median(x, cover = 0.5 - 1e-3, verbose = FALSE)
local_min(x, cover = 0.5 - 1e-3, verbose = FALSE)
local_max(x, cover = 0.5 - 1e-3, verbose = FALSE)
local_sd(x, cover = 0.5 - 1e-3, verbose = FALSE)
local_var(x, cover = 0.5 - 1e-3, verbose = FALSE)

## S3 method for class 'ursaRaster'
mean(x, ...)

## S3 method for class 'ursaRaster'
median(x, ...)

# non public
.average(x, cover = 0.5 - 1e-3, weight = NULL, sum = FALSE, verbose = FALSE)

Arguments

x ursaRaster object. In function local_mean and local_sum it is allowed to specify array with 3 dimensions (col, row, band) or (row, col, band)
cover Numeric. 0<=cover<=1 or >1. Quota for NA values in the location for all bands. Quota exceeding leads to recording NA value in the created map. If code>1 then number of bands. If 0<=cover<=1 then proportion cover to number of bands.
weight Positive numeric of length equal to number of bands. For local_mean and local_sum only. If specified, then weighted mean or sum are applied. The prior normalization is not required.
sum Logical. For .average only. If sum=TRUE then function returns sum of values else mean value.
verbose Logical. If verbose=TRUE then some output appears in console. Used for debug and benchark.
bandname Character. Band name for created single-band image.
... Function mean - arguments, which are passed to local_mean.
Function median - arguments, which are passed to local_median.

Details

If for valid output cell value it is required to have at least m values not marked as NA, specify quota as cover=m/nband(x).

local_mean and local_sum are wrapper to non-public function .average.

Generic functions mean, median, sd for ursaRaster class are implemented via local_mean, local_median, local_sd, respectively.
**local_stat**

Bundle of statistics, which is applied to each cell of multi-band image.

**Description**

If bands of ursaRaster object are interpreted as observations in time, then local_stat returns some parameters for time-series analysis. This is a local operation of map algebra.

**Usage**

```r
local_stat(obj, time = NULL, cover = 1e-06, smooth = FALSE, verbose = FALSE)
```

**Arguments**

- `obj` Object of class ursaRaster
- `time` Numeric or NULL. If NULL then regression parameters are for regular time-series using position of band in the brick (or, time=seq(obj)). If numeric, then length of time should be equal to number of bands of `obj`, and time is used to set irregularity for time-series.
**cover** Numeric. $0 \leq \text{cover} \leq 1$ or $>1$. Quota for NA values in the location for all bands. Quota exceeding leads to recording NA value in the cell of created band. If code$>1$ then number of bands. If $0 \leq \text{cover} \leq 1$ then proportion cover to number of bands. Default is $1e^{-6}$.

**smooth** Logical. If TRUE then median focal smoothing is applying to created 'slope' band; it is more suitable for visualization. Default is FALSE.

**verbose** Logical. Value TRUE provides some additional information on console. Default is FALSE.

**Value**
Object of class ursaRaster with bands:

- **mean** Mean value in each cell across all bands of source raster.
- **sd** Standard deviation in each cell across all bands of source raster. Denominator is n.
- **sum** Sum value in each cell across all bands of source raster.
- **min** Minimal value in each cell across all bands of source raster.
- **max** Maximal value in each cell across all bands of source raster.
- **n** Number of non-NA values in each cell across all bands of source raster (number of observations).
- **slope** Slope value in each cell across all bands of source raster.
- **slopeS** Significance of slope value taken with a sign of slope.
- **RSS** Residual sum of squares.
- **ESS** Explained sum of squares.

**Author(s)**
Nikita Platonov <platonov@sevin.ru>

**See Also**
Local statistics of map algebra, Group generics for objects of class ursaRaster.

**Examples**
```r
session_grid(NULL)
set.seed(353)
session_grid(regrid(mul=1/8))
a <- ursa_dummy(nband=15)
a[a<60] <- NA
cvr <- 12
b <- local_stat(a, cover=cvr)
print(b)
c.mean <- c('<bundle> mean'=b['mean'],
          '<generic> mean'=mean(a, cover=cvr))
```
c.max <- c('bundle> max'=b['max'],
         'local_max'=local_max(a,cover=cvr),
         'generic> max'=max(a,cover=cvr))
print(c.mean)
print(c.max)
cmp <- c(mean=b['mean']-local_mean(a,cover=cvr),
         sd=b['sd']-local_sd(a,cover=cvr))
print(round(cmp,12))
d <- as.list(b)
d[['slopeS']] <- colorize(d[['slopeS']],stretch="signif")
display(d,blank.density=20,blank.angle=c(-45,45))

na.omit

Drop bands which don’t have data.

Description

The bands with band_blank images, are omitted.

Usage

## S3 method for class 'ursaRaster'
na.omit(object, ...)

Arguments

object         Object of class ursaRaster.
...            Ignored. For consistence with definition of generic function.

Value

Object of class ursaRaster, which has no bands without any data.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

band_blank

Examples

session_grid(NULL)
session_grid(regrid(mul=1/4))
a <- ursa_new(value=1:3)
print(a)
a[2] <- NA
print(a)
a2 <- na.omit(a)
print(a2)
Get number of bands of raster image.

Description

`nband` (length) returns number of bands (layers, if appropriate in terminology) of `ursaRaster` object.

Usage

```r
nband(x)
## S3 method for class 'ursaRaster'
length(x)
```

Arguments

- `x` Object of class `ursaRaster`

Details

`length` for `ursaRaster` object is a synonym for `nband`.

Value

Positive integer of length 1.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

- `bandname` (names for `ursaRaster` object).

Examples

```r
session_grid(NULL)
a1 <- pixelsize()
print(a1)
print(nband(a1))
a2 <- c("Band 1"=a1,Band2=a1/2,sqrt=sqrt(a1),NA)
print(a2)
print(nband(a2))
```
open_envi

Description

open_envi creates object of ursaRaster class, reads ENVI header file and prepares connections for ENVI binary file.

Usage

open_envi(fname, resetGrid = FALSE, headerOnly = FALSE, decompress = !headerOnly, cache = 0L, ...)

Arguments

defname Filename; full-name or short-name
defresetGrid Logical. If TRUE then existing base grid (from session_grid) will be overwritten. Otherwise the spatial subsetting will be attempted.
defheaderOnly Logical. If TRUE then only reading of ENVI header file without creating connection to binary data; there is no necessary to decompress packed binary in this case. Default is FALSE.
defdecompress If ENVI binary file is compressed and you have not to use ENVI values then put decompress=FALSE to avoid useless operation
defcache Integer. Using cache for compressed files. If 0L then cache is not used. If 1L, then cache is used. Any value, which is differed from 0L and 1L, resets cache. Default is 0L.
def...

Details

open_envi try to find ENVI files (binary and header) and open them. If unsuccessful then function passes ...-arguments to create_envi function.

Value

Returns object of class ursaRaster. Values from ENVI binary are not in memory yet.

Author(s)

Nikita Platonov <platonov@sevin.ru>

dir(pattern="^example.*")
close(a)
envi_remove("example")

open_gdal  Open GDAL file

Description

open_gdal creates object of ursaRaster class, and prepares connections for data reading.

Usage

open_gdal(fname, verbose = FALSE)

ursa_open(fname, verbose = FALSE)

Arguments

fname  Character. Filename; full-name or short-name.

verbose  Logical. verbose=TRUE provides some additional information on console. Default is FALSE.

Details

ursa_open is a synonym to open_gdal. Generally, both function names are abridged version of ursa_open_gdal.

open_gdal doesn’t read data. Data can be read later using Extract operator .

If argument fname is ENVI .hdr Labelled Raster then either open_gdal or open_envi can be used. The former provides external implementation for data reading via GDAL in rgdal package.
panel_annotation

Add label or annotation to the image panel.

Description

panel_annotation puts an annotation (text label) on the panel with raster image without anchors to any layer. Can be used as captions to image panels.

Usage

panel_annotation(...)  

# non-public

.panel_annotation(label = expression(), position = "bottomright",  
lon = NA, lat = NA, x = NA, y = NA, cex = 1.0, adjust = 0.5,  
fg = "#000000", bg = "#FFFFFF1F", buffer = 1, fill = "#FFFFFF7F",  
font = par("family"), vertical = FALSE, alpha = 1,  
interpolate = FALSE, resample = FALSE, verbose = FALSE, ...)
Arguments

Set of arguments, which are recognized via their names (using regular expressions) and classes:

</table>

**label**

Character, expression, or objects of classes array or matrix. Text, symbols or logo for displaying on image panel. Multi-row characters are allowed with delimiter "\n". Default is expression().

**position**

Character keyword or numeric of length 2 in the interval [0,1]. Defines the location of scale bar. If character, then one of the "bottomleft", "bottomright", "topleft", "topright", "left", "right", "bottom", "top", or "center". If numeric then relative position on panel is defined using shift on horizontal and vertical axes from origin in the bottom-left corner. Default is "bottomright".

**lon**

Numeric. Longitude for center of annotation’s position. Default is NA.

**lat**

Numeric. Latitude for center of annotation’s position. Default is NA.

**x**

Numeric. The horizontal coordinate of the annotation’s position in the units of image grid. Default is NA.

**y**

Numeric. The vertical coordinate of the annotation’s position in the units of image grid. Default is NA.

**cex**

Positive numeric. The relative font size for annotation’s label. Default is 1. See description of argument cex in text function.

**adjust**

One or two values in [0, 1]. Specifies the horizontal (and optionally vertical) adjustment of the labels. See description of argument adj in text function.

**fg**

Character. Color name or code for label (texts and symbols). Default is "#000000" (black).
Character. Color name or code for thin buffer around label’s elements. Default is NA, which is interpreted as "transparent" for captions and as "#FFFFFF1F" for annotations.

Buffer

Numeric. The relative width of buffer around label’s elements. Default is 1.

Fill

Character. Color name or code for circumscribed rectangle around labels. Default is NA, which is interpreted as "#FFFFFF7F" for captions and as "transparent" for annotations.

Font

Character. Font family. Default is getOption("ursaPngFamily"), which is specified by argument font (or family) in compose_open()....
Examples

```
session_grid(NULL)
## exam no.1 -- direct use
compose_open(layout=c(2,3),legend=NULL,device="cairo")
for (i in seq(6)) {
  panel_new()
  panel_annotation(label=LETTERS,cex=1.5)
  panel_annotation(pos=c(0.7,0.2),
  ,label=paste("panel",paste("no.",i),sep="\n"))
  if (i==1)
    panel_annotation(pos="center")
}
compose_close()

## exam no.2 -- indirect use
display(pixelsize(),scale=2
  ,ann.label="FJL",ann.lon=52,ann.lat=80,ann.buffer=1
  ,ann.bg="#8F6FFF2F",ann.fill="#FFFF7F9F",ann.font="courier")
```

panel_coastline

Add coastline to the image panel.

Description

panel_coastline puts a coastline to the active panel of layout with optional land shadowing. The package provides data for coastline.

Usage

compose_coastline(...)

panel_coastline(...)

update_coastline(merge = TRUE)

# not public
.compose_coastline(obj = NULL, panel = 0, col = NA, fill = "transparent",
  detail = NA, density = NA, angle = NA, land = FALSE,
  lwd = 0.5, lty = 1, fail180 = NA, verbose = FALSE)

# not public
.panel_coastline(obj, verbose = FALSE)

Arguments

... Set of arguments, which are recognized via their names (using regular expressions) and classes:
<table>
<thead>
<tr>
<th>Matched pattern</th>
<th>Used name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coast(line)*</td>

</tbody>
</table>

**obj** Objects of the one of the classes Spatial, sfc, ursaCoastLine. The last one is internal structure, which is returned by function compose_coastline.

**panel** Integer vector. Panel for which coastline will be displayed. 0L means that coastline will bw displayed for all panels. Default is 0L.

**col** Character. Color code/name for coastline. Default is "grey60".

**fill** Character. Color code/name for land masking/shadowing. Default is "transapent".

**detail** Character keyword. The categorical spatial resolution for coastline. Valid values are "l" (low), "m" (medium), "h" (high), "f" (full). If value is NA, then coastline resolution is selected internally. Default is NA.

**density** Numeric. The density of shading lines for land masking/shadowing. If NA then no shading lines are drawn. Default is NA. See density in polygon.

**angle** Numeric. The slope of shading lines, given as an angle in degrees (counterclockwise). If NA then no shading lines are drawn. Default is NA. See angle in polygon.

**land** Logical. If TRUE then map’s accent is to land, and ocean is masked/shadowed. If FALSE then map’s accent is to ocean, and land is masked/shadowed. Default is FALSE.

**lwd** Positive numeric. Width of coastline. Default is 1. See lwd in par.

**lty** Positive integer. Type (pattern) of coastline. Default is 1L (solid). See lty in par.

**fail180** Logical. Patch for correct plotof polygons crossing 180 degree longitude. NA means than decision is taken intuitively. TRUE forces to implement crossing og 180 degree longitude. FALSE forces to not implement crossing og 180 degree longitude. Default is NA.

**verbose** Logical. Value TRUE may provide some additional information on console. Default is FALSE.

**merge** Logical. Ignored.
Details

compose_coastline forms an object of class ursaCoastLine. panel_coastline displays object of class ursaCoastLine. It is expected higher performance for multi-panel plotting.

If obj is NULL, then internal data is used. This data is based on simplified polygons of OpenStreetMap-derived data. Source data is licensed under the Open Data Commons Open Database License (ODbL). The crossing longitude 180 degrees polygons are merged. Removing of small polygons and simplifying of polygons geometry is applied for three levels of details ("l" - low, "i" - interim, "h" - high). For the full ("f") level of details data simplification is not applied.

Coastline data are taken from directory, which is specified by getOption("ursaRequisite") with default value system.file("requisite",package="ursa"). Package contains data of "l" (low) details level in the file system.file("requisite/coast-l.rds",package="ursa"). Data of higher levels can be added using update_coastline() function. It is required to specify user's requisite path using options(ursaRequisite=path/to/user/files) before loading ursa, e.g. in the user's ~/.Rprofile file. Otherwise, there is a chance that data can not be updated due to 'permission deny' of the system directories. Package sf and some it's suggestions are required for data update.

If detail=NA then the spatial resolution is selected using CRS boundary and resolution using intuitive approach. If package's database cannot supply required details, then lower resolution is used.

Source coastline data in EPSG:4326 are transformed to CRS projection, extracted using session_grid function. Coastlines with optional filling of either land or ocean area is interpreted as polygons. If filling is solid (there is no transparency or shading lines (numerical values of arguments density and angle), then coastline plotting is implemented via polypath function, otherwise polygon function.

Value

panel_coastline returns NULL
compose_coastline returns of object of class ursaCoastLine. It is a list:

coast_xy Two-column matrix of coordinates in the sessional projection. The polygons are separated by c(NA,NA) rows.
panel Integer. Panel for coastline displaying. If 0L, then coastline is displayed on each panel.
col See description of argument col.
fill See description of argument fill.
shadow If filling is semi-transparent, then it is "alpha" of filling color (argument fill).
land See description of argument land.
density See description of argument density.
angle See description of argument angle.
lwd See description of argument lwd.
lty See description of argument lty.

License

Coastal data (land polygons) is distributed under ODbL.
**Note**

In the versions <=3.7-19 package ursa contained land polygons based on union of "GSHHS_L1_L1.shp" and "GSHHS_L1_L5.shp" data from Self-consistent Hierarchical High-resolution Geography Database (GSHHG), Version 2.3.3 (01 November 2014), distributed under the Lesser GNU Public License, Version 3 (29 June 2007).

    panel_annotation(pos=c(0,1),text="ocean is masked")
}
compose_legend(p2,p1)
compose_close()
```

**_panel_contour_**

Add colored contour to the image panel
Description

An instrument to overlay multiple rasters on the same image panel. Contour is derived from one band of raster image. The colors (and respective colorbar in legend) is an alternative to contour labeling.

Usage

panel_contour(obj, type = "", ...)
panel_contour

verb(ose)* Logical. Value TRUE may provide some additional information on console. Default is FALSE. Other arguments are used in the function colorize to produce color tables.

Details

Function contourLines is used for contouring.

The color table of input raster image is kept. The output panel have one element left, because contours are borders between areas of the same color. It is recommended to use only gradient palettes.

The color table is forced not to be ramp (argument ramp=FALSE in the function colorize) to prevent extra density of contour lines.

The color table is forced to be interval (argument interval=1L in the function colorize) to prevent lost of elements in the palette.

Value

Object of class ursaColorTable, which then should be used as an input argument for the colorbar legend (function legend_colorbar). If there is no argument of class ursaRaster then function returns NULL value.

}

### panel_decor

Add auxiliary elements to the plotting panel.

#### Description

panel_decor adds over plot sequentially the followed elements: coastline, gridline, scalebar. Unlike panel_decor, function layout.grid does not add scalebar.

#### Usage

panel_decor(...)

#### Arguments

... Passed to sequence of plotting functions:

- **panel_graticule.** To distinguish the same argument names in different functions it is provided to use prefix “grid.*”, e.g., grid.col="grey40”.
- **panel_coastline.** To distinguish the same argument names in different functions it is provided to use prefix “coast.*”, e.g., coast.col="grey60”.
- **(not applicable for layout.grid)** panel_scalebar. To distinguish the same argument names in different functions it is provided to use prefix “scalebar.*”, e.g., scalebar.col="black”.

#### Details

The sequence of elements is constant. To change order, use direct calling of panel_graticule, panel_coastline, panel_scalebar in any sequence.

Sometimes, for rasters with NA values the followed sequence may be used:

panel_coastline(col="transparent",fill="grey80")
panel_raster(a)
panel_coastline(col="grey40")

#### Value

panel_decor returns NULL value.
layout.grid returns NULL value.

#### Author(s)

Nikita Platonov <platonov@sebin.ru>
Examples

```r
session_grid(NULL)
a <- ursa_dummy(nband=1,min=0,max=100)
a[a<30] <- NA
compose_open()
pnad_new()
ct <- panel_raster(a)
pnad_decor(graticule.col="green4",graticule.lwd=2, scalebar.col="brown")
compose_legend(ct)
compose_close()
```

panel_graticule

**Add latitude/longitude or metric grid to the image panel.**

Description

`panel_graticule` puts a grid on the panel with raster image. If CRS is georeferenced then grid is generated from longitudes and latitudes.

Usage

```r
panel_graticule(...)
```

```r
compose_graticule(...)
```

# non-public
```r
.compose_graticule(panel = 0L, col = "grey70", border = "grey70", lon = NA, lat = NA,
                   lwd = 0.5, lty = 2, marginalia = rep(FALSE, 4), trim = FALSE,
                   language = NA_character_, cex = 0.75, verbose = FALSE)
```

# non-public
```r
.panel_graticule(obj, marginalia = rep(TRUE, 4), verbose = FALSE)
```

Arguments

... 

Set of arguments, which are recognized via their names (using regular expressions) and classes:

<table>
<thead>
<tr>
<th>Matched pattern</th>

</tr>
</tbody>
</table>
panel_graticule

Objects of the class ursaGridLine. It is internal structure, which is returned by function .compose_graticule.

**panel**
Integer vector. Panel for which coastline will be displayed. 0L means that coastline will be displayed for all panels. Default is 0L.

**col**
Character. Color code/name for grid lines. Default is "grey70".

**border**
Character. Color code/name for marginal labels and ticks. Default is "grey70".

**lon**
Numeric vector. Set of longitudes for grid. If NA then set of longitudes is formed internally. Default is NA.

**lat**
Numeric vector. Set of latitudes for grid. If NA then set of latitudes is formed internally. Default is NA.

**lwd**
Positive numeric. Width of grid line. Default is 0.5. See lwd in par.

**lty**
Positive integer. Type (pattern) of grid line. Default is 2 (dashed). See lty in par.

**marginalia**
Logical or integer vectors. Responsible for whether longitudes and latitudes (or metric coordinates) be labelled on the frame of panel with raster image. If logical and TRUE, then labels will be displayed on each open side of panel. If logical and FALSE then labels will not be displayed. If logical of length 4, then labels will be displayed on specific side, where side index is c(bottom,left,top,right) (see description for marginal parameters in par). If argument is a vector of positive integers, then labels for grid lines are plotted only for the specified panels, which sequence is defined in compose_design function and returned from getOption("ursaPngLayout")$layout. Default is c(TRUE,TRUE,TRUE,TRUE).

**language**
Character. Language for longitude and latitude captions. If "ru" then captions are in Russian else in English. Default is NA.

**trim**
Logical. If grid lines are labelled then trim=TRUE prevents crossing the labels on neighbor perpendicular sides.

**cex**
Positive numeric. The relative font size for grid lines’ labels. Make sense in the case of labels plotting. Default is 0.75.

**verbose**
Logical. Value TRUE may provide some additional information on console. Default is FALSE.

**Details**
If not language="ru" but environmental variable LANGUAGE=ru then labels are in Russian (cyrillics).

Argument gridline (or, grid) is introduced for unconditional calling of panel_graticule inside of high-level functions.

Grid lines can be controlled in high-level plot functions (e.g., display, compose_plot, display_stack, display_brick, display_rgb, etc.). To prevent displaying grid lines, use argument gridline=FALSE.
(or grid=FALSE). To display grid lines, use argument gridline=TRUE (or grid=TRUE) and prefix grid(line)* (gridline.* or grid.* ) for grid lines' parameters, e.g., gridline.verb=TRUE, grid.col="black". If prefix is omitted then arguments with the same names affect in other functions in the part of high-level function.

If grid lines are formed internally, then desirable number of lines for each direction is 3. The design of line density is based on intuition, providing pretty labelling.

If CRS is georeferenced then grid lines are corresponded to longitudes and latitudes. Integer minutes are used to illustrate fractional values of degrees. If precision of minutes is insufficient, then integer values of seconds are introduced. The fractional values of seconds are not used.

Labels are located at the points, where grid lines cross plot margin. Labels are not overlapped along the same side. To prevent overlapping along the same side, labels are shifted or omitted. Argument trim=TRUE prevents overlapping labels from neighbor sides via hidding.

Value

Function returns NULL value.

## Changing of environmental variables is out of CRAN Policy
## Not run: Sys.setenv(LANGUAGE="") # reset environmental variable

| panel_new | Start plotting on the new image panel |

Description

panel_new finishes plotting on previous image panel and starts plotting on next image panel.

Usage

panel_new(...)

# non-public
.panel_new(col = "chessboard", density = NA, angle = NA, lwd = 1, lty = 1,
  asp = NA, mar = rep(0, 4), verbose = FALSE)

Arguments

... Set of arguments, which are recognized via their names (using regular expressions) and classes. Passed to non-public .panel_new. Optional prefix "blank" is used for indirect use. Separated by a dot ".", e.g., blank.fill="transparent".

<table>
<thead>
<tr>
<th>Pattern (panel_new)</th>
<th>Argument (.panel_new)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(blank.)*(^{bg</td>
<td>bg})[fill]</td>
<td>col</td>
</tr>
<tr>
<td>(blank.)*density</td>
<td>density</td>
<td>See below.</td>

<td>verbose</td>
<td>See below.</td>
</tr>
</tbody>
</table>
**panel_new**

- **col** Character. Color code/name for panel filling/shadowing. Default is "grey80" for georeferenced images, and "grey90" for non-projected images.

- **density** Numeric. The density of shading lines for fill/shadowing. If NA then no shading lines are drawn. Default is NA. See density in rect.

- **angle** Numeric. The slope of shading lines, given as an angle in degrees (counterclockwise). If NA then no shading lines are drawn. Default is NA. See angle in rect.

- **lwd** Positive numeric. Width of coastline. Default is 1. See lwd in rect.

- **lty** Character or positive integer. Type (pattern) of coastline. Default is 1L (solid). See lty in rect.

- **asp** Positive numeric. The y/x aspect ratio. Default is 1. See asp in plot.window.

- **mar** Positive numeric of length 4. Plot margins. Default is rep(0,4L). See mar in par.

- **verbose** Logical. Value TRUE may provide some additional information on console. Default is FALSE.

**Details**

Prefix blank is introduced for manipulations with panel_new inside of high-level functions (e.g., display). Prefix skipping is the subject for conflict with functions, which use the same name of arguments.

It is required to call panel_new for every image panel. First calling starts plotting on the first panel. Second and next callings change image panels.

The panel sequence is set in function compose_design, which is called directly or indirectly from compose_open, and keeps in the options (access via getOption("ursaPngLayout")$layout).

Image background is formed via consecutive call of functions plot(...,type="n"), and rect(...).

**Value**

Function returns NULL value.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**Examples**

```r
session_grid(NULL)
# example no.1 -- direct use
compose_open(layout=c(1,2),legend=NULL)
panel_new()
panel_annotation(label="Default + Empty")
panel_new(col="#0000FF3F",density=15,angle=45,lwd=3)
panel_decor()
panel_annotation(label="Settings + Grid")
compose_close()
```
# example no.2 -- indirect use
a <- pixelsize()
a <- a[a>560]
display(a,blank.col="#0000FF3F",blank-density=15,blank-angle=45,blank.lwd=3
,coast.fill="#007F005F",coast.density=20,coast.angle=c(-30,60))

panel_plot

Add graphical elements to the image panel

Description

Standard functions for plotting from package graphics are used for manual adding elements to current plot. These series of functions used that standard instruments with additional controlling the acceptability of plotting.

Usage

panel_plot(obj,...)

panel_box(...)  
panel_lines(...)  
panel_points(...)  
panel_text(...)  
panel_abline(...)  
panel_polygon(...)  
panel_segments(...)

Arguments

obj  
R object.

...  
In panel_plot arguments are passed to function plot.  
In panel_box arguments are passed to function box.  
In panel_lines arguments are passed to function lines.  
In panel_points arguments are passed to function points.  
In panel_text arguments are passed to function text.  
In panel_abline arguments are passed to function abline.  
In panel_polygon arguments are passed to function polygon.  
In panel_segments arguments are passed to function segments.

Details

If unable to get value TRUE fromgetOption("ursaPngPlot") then plotting is disable, and any function from this series returns NULL.

Generally, for spatial objects argument add=TRUE is used in panel_plot.
Value

For spatial objects (simple features from \texttt{sf} or spatial abstract classes from \texttt{sp}) function \texttt{panel_plot} returns object of class \texttt{ursaLegend}. It is a list with items, which can be used to as arguments of \texttt{legend()}. This is intermediate step for experimental feature (not ready) to display colorbars on plot panel. For other objects function \texttt{panel_plot} returns value of function \texttt{plot}.

Function \texttt{panel_box} returns value of function \texttt{box}.
Function \texttt{panel_lines} returns value of function \texttt{lines}.
Function \texttt{panel_points} returns value of function \texttt{points}.
Function \texttt{panel_text} returns value of function \texttt{text}.
Function \texttt{panel_abline} returns value of function \texttt{abline}.
Function \texttt{panel_polygon} returns value of function \texttt{polygon}.
Function \texttt{panel_segments} returns value of function \texttt{segments}.

Note

For plotted elements it is possible to create legend for colors using color bars. No shapes kind and size, no line widths.

To convert object \texttt{x} of class \texttt{ursaLegend} to object of class \texttt{ursaColorTable} please use \texttt{ursa_colortable(x)}.

  ,pattern=paste0(layername,\\.\.(cpg|dbf|prj|shp|shx)"))
  ,full.names=TRUE))

panel_raster  

Add raster to the image panel

Description

If specified image has 3 or 4 bands, then color composite is plotted on image panel, else the image is plotted regarding to its color table.

Usage

panel_raster(...) 

Arguments

... 

Set of arguments, which are recognized via their names (using regular expressions) and classes.
1. Passed to colorize.
2. interpreted in this function:

  "\$|\(obj\)" as \(obj\) Object of class ursaRaster. Raster band for plotting. Multiple bands are allowed if then can be interpreted as RGB or RGBA.
"useRaster" as useRaster Logical. If TRUE then a bitmap raster is used to plot the image instead of polygons. See argument useRaster in function image. Default depends on PNG device (getOption("ursaPngDevice"), which is set up in compose_open); it is TRUE for "cairo" device, and FALSE for "windows" device.

"interp(olate)*" as interpolate Logical. Passed as argument interpolate to function rasterImage.

"(alpha|transparen(cy)*)*" as alpha Numeric or character. Level of transparency. If numeric, the either 0 <= alpha <= 1 or 0 <= alpha <= 255. If character, then one byte of hexadecimal value "00" <= alpha <= "FF". If NA, then transparency is used from colortable, else transparency of colortable is overwritten by alpha. Default is NA.

"verb(ose)*" as verbose Logical. Value TRUE may provide some additional information on console. Default is FALSE.

Details

If obj is list of raster images, then panel_raster is applied to each item of list, and colortable of last item is returned.

If obj has 3 or 4 bands then obj is interpreted as RGB(A) image.

Function attempts to speed up plotting by reduce image matrix for big rasters.

Value

If argument obj has strictly one band, then function returns color table - object of class ursaColorTable, which can be used as an input argument for the colorbar legend (function legend_colorbar). Otherwise function returns NULL value.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
# example no.1 -- direct use
session_grid(regrid(mul=1/32))
dima <- with(session_grid(),c(columns,rows,3))
a <- ursa_new(value=array(runif(prod(dima),min=127,max=255),dim=dima))
p <- colorize(a,pal=c("black","white"),ramp=TRUE,value=0:256)
compose_open(layout=c(2,3),skip=4,legend=list(list("top","full"),list("bottom",2:3)))
for (i in seq(6)) {
  panel_new()
  if (i<4)
    panel_raster(p[i])
  else
    panel_raster(a,interpolate=i==5)
  panel_decor(col="black",coast=FALSE)
  panel_annotation(c("red","green","blue"
    ,"interpolate=FALSE","interpolate=TRUE"))
```
panel_scalebar

Add scale bar to the image panel

Description

panel_scalebar puts a scale bar (’box’ style) on the panel with raster image.

Usage

panel_scalebar(...)

non-public

.panel_scalebar(position = "bottomleft", w = NA, cex = 0.85,
    col = "#0000002F", bg = "transparent", fill = "#FFFFFF2F",
    language=NA, verbose = FALSE)

Arguments

... Set of arguments, which are recognized via their names (using regular expressions) and classes. Passed to non-public .panel_scalebar, excepting argument scalebar:

Pattern (panel_scalebar) Argument (.panel_scalebar) Description
(scalebar|ruler|decor) (scalebar\.)*pos(ition)* position See below.
(scalebar\.)*w w See below.
(scalebar\.)*cex cex See below.
(scalebar\.)*col col See below.
(scalebar\.)*fill fill See below.
(scalebar\.)*bg bg See below.
(scalebar\.)*language language See below.
(scalebar\.)*verb(ose)* verbose See below.
position Character keyword or numeric of length 2 in the interval [0,1]. Defines the location of scale bar. If character, then one of the "bottomleft", "bottomright", "topleft", "topright", "left", "right", "bottom", "top", or "center". If numeric then relative position on panel is defined using shift on horizontal and vertical axes from origin in the bottom-left corner. Default is "bottomleft".
w Positive numeric. The length in km of scalebar's right segment. If w=NA then length of segment is defined automatically. Default is NA.
cex Positive numeric. The relative font size for scalebar's labels. Default is 0.85.
col Character. Primary fill color for scalebar box and scalebar labels. Default is "#0000002F".
fill Character. Secondary fill color for scalebar box. Default is "#FFFFFF2F".
bg Character. Background color for the area of scalebar box and labels. Default is "transparent".
language Character. Language for longitude and latitude captions. If "ru" then captions are in Russian else in English. Default is NA.
verbose Logical. Value TRUE may provide some additional information on console. Default is FALSE.

Details

The scalebar has 2 left segments and 2 right segments. Left and right segments are separated by 0. The length of left segments is a half of length of right segments.

Argument scalebar (or, synonym, ruler) is introduced for unconditional calling of panel_scalebar inside of high-level functions.

Default x=0 and y=0 define the "bottomleft" position of scale bar.

If argument scale in the function compose_open is character, then the length of one segment is exactly 1 cm, and the total length of scalebar is 3 cm.

If not language="ru" but environmental variable LANGUAGE=ru then labels are in Russian (cyrillics).

The length distortions is taken into account for transverse Mercator ("+proj=tmerc") projection regarding to location of scalebar.

Scalebar (single occurrence) can be controlled in high-level plot functions (e.g., display, compose_plot, display_stack, display_brick, display_rgb, etc.).

To plot scalebar, use argument scalebar=TRUE and prefix (ruler|scalebar) (scalebar.* or ruler.*) for scalebar's parameters, e.g., scalebar.pos="bottomright", scalebar.cex=0.9.

Scalebar is not displayed for longlat projection ("+proj=longlat"), where units are degrees.

Value

This function returns NULL value.

panel_shading

**Examples**

```r
session_grid(NULL)
# example no.1 -- direct usage
a <- colorize(pixelsize())
compose_open(a)
panel_new()
panel_raster(a)
panel_scalebar()
compose_close()

# example no.2 -- indirect usage
display_rgb(ursa_dummy(nband=3,min=0,max=255)
  ,scalebar=TRUE,scalebar.col="white",scalebar.fill="black")

# example no.3 -- for paper copy
a <- colorize(pixelsize(),breakvalue=seq(400,650,by=50),palname="Greys",inv=FALSE)
compose_open(scale="1:95000000",dpi=150,device="cairo",family="Times")
compose_plot(a,gridline=FALSE,scalebar=TRUE,scalebar.x=1,units=expression(km^2))
compose_close(bpp=8)

# example no.4 -- length distortion in the Transverse Mercator projection
a1 <- regrid(setbound=c(10,65,71,83),dim=c(100,100),crs=4326)
a2 <- polygonize(ursa_bbox(a1))
a3 <- spatial_transform(a2,3857)
a4 <- regrid(setbound=spatial_bbox(a3),res=20000,crs=spatial_crs(a3))
compose_open(legend=NULL)
panel_new("white")
panel_coastline(fill="#00000010")
# panel_graticule()
for (p in c("bottom","center","top"))
  panel_scalebar(pos=p,w=200)
compose_close()
```

**panel_shading**

*Shaded overlay by image mask*

**Description**

This specific function is designed to illustrate linear slope and areas of statistically significant slope on the same panel, however can be used commonly for shading by raster mask.

**Usage**

```r
panel_shading(obj, level = NA, col = NULL, density = 25, angle = c(-45, 45),
  lwd = 1, lty = 1, verbose = TRUE)
```
Arguments

obj  Object of class ursaRaster.
level  Positive numeric. Threshold for obj reclassification { obj<(-level) | obj>(+level) }. If NULL then mask is created from non-NA values of obj. Default is NULL.
col  ursaColorTable (ursaRaster with color table) or character. Color for shading lines (grid). If object of class ursaColorTable. Two colors on the limits of color vector are extracted to separate source values <=(-level) and >=(+level).
density  Numeric. The density of shading lines, in lines per inch. Default is 25. See description of argument density in function polygon.
angle  Numeric. The slope of shading lines, given as an angle in degrees (counterclockwise). Default is vector of length two c(-45,45). See description of argument angle in polygon function.
lwd  Numeric. Line width for shading. Default is 1. See description of lwd in par function.
lty  Numeric or character. Line type for shading. Default is 1. See description of lty in par function.
verbose  Logical. If TRUE then progress bar is appeared. Default is TRUE.

Details

Values of input obj is reclassified to raster mask: { values<=(-level) OR values>=(+level) }. For common use, select appropriate level and, if necessary, reclassify obj prior. Color limits are extracted using range function.

Raster images can be used for colored shading using alpha argument of panel_raster function, e.g. panel_raster(a,alpha=3/4)

Value

NULL

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
if (first.example <- TRUE) {
  session_grid(NULL)
  session_grid(regrid(mul=1/8))
  ps <- pixelsize()
  compose_open()
  ct <- compose_panel()
  panel_shading(ps>1.1*global_mean(ps),angle=90)
  compose_legend(ct)
  compose_close()
```
if (second.example <- TRUE) {
    session_grid(NULL)
    a <- ursa_dummy(nband=15,mul=1/8)
    b <- local_stat(a)
    compose_open()
    lev <- 0.90
    d <- as.matrix(b["slopeS"],coords=TRUE)
    e <- contourLines(d,levels=c(-lev,lev))
    p <- list(significance.raw=colorize(b["slopeS"])
              ,significance.formatted=colorize(b["slopeS"],stretch="significance")
              ,slope=colorize(b["slope"]))
    p <- c(p,rep(p[3],3))
    names(p)[c(3,5)] <- c("Slope and shaded significance"
                         ,"Slope and contoured significance"
                         ,"Slope and 'contourLines'")
    compose_open(p,layout=c(2,NA),byrow=FALSE)
    compose_panel(p[1])
    compose_panel(p[2])
    compose_panel(p[3])
    panel_shading(b["slopeS"],level=lev)
    compose_panel(p[4])
    panel_contour(b["slopeS"],value=c(-lev,lev))
    compose_panel(p[5])
lapply(e,panel_polygon)
    compose_panel(p[6])
    ct <- panel_contour(b["slopeS"],"color"
                        ,value=c(-0.99,-0.95,-0.9,-0.5,0.5,0.9,0.95,0.99))
    compose_legend(c(head(p,-1),'(Colorbar for contours')=list(ct)),las=3)
    compose_close()
}

pixelsize <- function(obj, verbose = FALSE) {
    # The actual size of each grid cell with considerable distortion in area of map projection.
    # This function helps to calculate size of pixels in the unit of area (squared km) for zonal statistics
    # with taking into account distortion in area for classes of projections.
    # Usage
    # pixelsize(obj, verbose = FALSE)
    # Arguments
    # obj Either ursaRaster object or ursaGrid object or NULL or missing.
    # verbose Logical. Value TRUE may provide some additional information on console. Default is FALSE.
Details

pixelsize() is applied to coordinate reference system (grid) of ursaRaster object or to raster grid directly. If argument obj is missed, then session grid is used.

Currently, only Stereographic (+stere" in PROJ.4 notation), Mercator (+merc), and Lambert Azimuthal Equal Area (+laea) classes of map projections are implemented, though the last one (LAEA) has no distortion in area.

Value

Object of class ursaRaster, single-band. If size of cell is more than 10e5 square meters, then the unit is squared kilometers (band name is "Pixel Size (sq.km)") else squared meters (band name is "Pixel Size (sq.m)").

```

---

**polygonize**  
*Raster to vector (polygon) conversion.*

**Description**

Representing each raster cell as a polygon. In comparison to common GIS raster to vector conversion, where neighbor cells with the same value are combined to the single polygon, the number of output polygons is equal to number of non-NA values.

**Usage**

```r
polygonize(obj, fname, engine = c("native", "sp", "sf"), verbose = NA, ...)
```

**Arguments**

- `obj` Object of class `ursaRaster`.
- `fname` Missing or character. If specified, then ESRI Shapefile is created. Default is missing.
- `engine` Character keyword from list `c("native", "sp", "sf")`. Define package with tools for creating spatial data. If `engine="sp"`, then functions from package `sp` are used. If `engine="sf"`, then functions from package `sf` are used. If `engine="native"`, then appropriate package is used based on loaded namespaces before.
- `verbose` Logical. If TRUE then conversion is attended by progress bar. Default is NA; it means TRUE for engine="sp" and FALSE for engine="sp".
- `...` Additional arguments, which are passed to internal function for writing ESRI Shapefile.
  - `compress` Logical. Should output ESRI Shapefile files be compressed by zip? Default is FALSE.

**Details**

Some GIS software (e.g., QGIS) has broad tools for display vector data. Excepting choroplets, it is assumed that visualization of each cell separately is more attractive than displaying of polygons with different forms, which are produced, for example, by GDAL conversion utility `gdal_polygonize.py`. 
**Value**

If missing `fname` and tools from `sp` then object of class "SpatialPolygonsDataFrame" (package `sp`). If missing `fname` and tools from `sf` then object of class "sf" with geometry of class "sfc_POLYGON" (package `sf`). If `fname` is specified, then `NULL`.

**Note**

Implementation is very slow even for moderate image size. Use progress bar (`verbose=TRUE`) to control this process.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**Examples**

```r
session_grid(NULL)
a <- ursa_dummy(mul=1/16)
a <- a[a>100]
print(a)
print(band_mean(a))
b2 <- polygonize(a,engine="sp") ## try 'engine="sf"'
print(colMeans(spatial_data(b2),na.rm=TRUE))
print(ursa_bbox(a))
print(spatial_bbox(b2))
```

---

**Description**

Reads all or several bands of ENVI .hdr Labelled Raster file from disk to memory.

**Usage**

```r
read_envi(fname, ...)
```

**Arguments**

- `fname`  
  Character. Filename for ENVI .hdr Labelled Raster file.

- `...`  
  For `read_envi`: Set of arguments, which are recognized via their names (using regular expressions) and classes. In the case of grids mismatch some arguments (e.g., `resample`) are passed to `regrid` function.
**Details**

Function `read_envi` is designed to one-time reading (from disk to memory) ENVI .hdr Labelled Raster file. For multiple access to disk (by chunks), use followed construction:

```r
a <- open_envi(fname)
d1 <- a[condition_1]
d2 <- a[condition_2]
...
close(a)
```

In this case, the connection keeps open. The gain is more effective for compressed binary files.

**Value**

Object of class `ursaRaster`.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**See Also**

- `open_envi`, `Extract` method [ for `ursaRaster` object, `close_envi`.
- `read_gdal` uses GDAL (`rgdal`) to read ENVI .hdr Labelled Raster file.

**Examples**

```r
session_grid(NULL)
fname <- tempfile()
a <- ursa_dummy()
bandname(a) <- c("first","second","third")```
write_envi(a,fname,compress=FALSE)

print(read_envi(fname))
print(read_envi(fname,c(1,3)))
print(read_envi(fname,-c(1,3)))
print(read_envi(fname,c("first","third")))
print(read_envi(fname,"iR"))

print(session_grid())
g <- regrid(session_grid(),mul=1/2.3)
b <- read_envi(fname,ref=g)
print(session_grid())
print(b)
envi_remove(fname)

**read_gdal** 
*Read GDAL supported raster files.*

**Description**

read_gdal creates ursaRaster object from GDAL supported raster files using functions from *rgdal* packages.

**Usage**

```r
read_gdal(fname, resetGrid = TRUE, band = NULL, engine = c("native", "rgdal", "sf"),
          verbose = FALSE, ...)

ursa_read(fname, verbose = FALSE)
```

**Arguments**

- **fname** Character. GDAL supported raster file name.
- **resetGrid** Logical. If TRUE then new sessional grid is based on opened raster image. Default is TRUE.
- **band** Character (regular expression) or integer.
- **engine** Character. Functionality of which package is used for reading data. If partial data (band is not NULL), then engine is "rgdal". If value is "sf" and no partial data reading then sf::gdal_read() is used before importing. If value is "rgdal" or partial data reading, then interaction with *rgdal* is used. Currently, "native" is similar to "rgdal", but in next versions behaviour can be changed to engine selection depends on which namespace has already loaded or has suggested package *sf* been installed.
- **verbose** Logical. Value TRUE may provide some additional information on console. Default is FALSE.
- **...** Ignored.
Details

\texttt{ursa_read} is simplified implementation of \texttt{gdal_read}.

The composite GDAL formats (e.g., NetCDF: Network Common Data Format, HDF5: Hierarchical Data Format Release 5) are likely unsupported.

\texttt{read_gdal} uses functions from \texttt{rgdal}:

- \texttt{GDALinfo} - to get raster metadata.
- \texttt{getRasterData} - to get raster data.

Category names and color tables are supported.

Value

Object of class \texttt{ursaRaster}.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

\texttt{rgdal::GDALinfo()} for supported GDAL raster formats
\texttt{as.ursa} is an alternative call for GDAL raster files import.

Examples

\begin{verbatim}
session_grid(NULL)
rgdal::gdalDrivers()
Fin1 <- system.file("pictures/Rlogo.jpg",package="rgdal")
a1 <- read_gdal(Fin1)
print(a1)
display(a1)

Fin2 <- system.file("pictures/test_envi_class.envi",package="rgdal")
b1 <- read_gdal(Fin2)
b2 <- read_envi(Fin2,resetGrid=TRUE)
print(identical(ursa_grid(b1),ursa_grid(b2)))
print(identical(ursa_value(b1),ursa_value(b2)))
print(identical(ursa_colortable(b1),ursa_colortable(b2)))
print(ursa_colortable(b1))
print(as.table(b1))
display(b1,detail="l")
\end{verbatim}
reclass

Reclassify specific values of image

Description

This is look-up table reclassification: the destination value is found for each source value.

Usage

reclass(obj, dst = NULL, src = NULL, sparse = FALSE, ...)

Arguments

obj
Object of class ursaRaster or ursaColorTable.
dst
Object of class ursaRaster, or object of class ursaColorTable, or numeric vector. If numeric, then the desired destination set of values, else reference object for reclassification; this object should have numerical values of categories.
src
Numerical vector, but allowed using with numerical vector of dst and length(src)==length(dst). Source set of values.
sparse
Logical. If image has a lot of NA values then sparse=TRUE may speed up transformation. Default is FALSE.
...
Other arguments are used for classification in the function colorize.

Details

If dst is numeric vector, then the source value have to be specific, without any ranges. It is required the equality lengths of src and dst. If image has color table then function tries reconstruct dst from names of categories.
This function can be used for data compression for storage, e.g. for distribution or interchange.

Value

If obj is object of class ursaColorTable then numeric vector of categories’ centers.
If dst is numeric, then object of class ursaRaster without color table.
If dst is ursaColorTable then object of class ursaRaster (NA values) in color table.
If dst is NULL then object of class ursaRaster with empty color names (NA values) in color table.

Note

There were no a lot of tests how GIS software reads "ENVI .hdr Labelled Raster" files with color tables without color values (only categories). At least, GDAL recognizes categories (gdalinfo utility).

b3 <- reclass(a[2],ursa_colortable(b2))
b <- c(b1,b2,b3)
print(reclass(b))

# example no.3 -- compression with data lost
a <- pixelsize(NULL)
b <- reclass(a,byte=TRUE,tail=0)  ## try 'byte=FALSE'
a2 <- reclass(b)
res <- c(source=a,as_category=a2,difference=a-a2)
print(res)
message(paste("RMS error: ",format(sqrt(band_sum(res[3]^2)/band_n(res[3])))))
prefix <- paste0(prefix,".envi")
fname <- file.path(tempdir(),paste0(prefix,",envi\"))
s <- data.frame(object.size=sapply(list(a,b),object.size))
rownames(s) <- prefix
print(s)
write_envi(a,fname[1])
write_envi(b,fname[2])
f <- file.info(dir(path=tempdir(),pattern=paste0("",".envi\"),sep="\")
co1names(f) <- "file.size"
print(f)
envi_remove(fname)
\end{verbatim}

\texttt{regrid} \hspace{1cm} \textit{Change raster image resolution and extent}

Description

General function to change parameters of cells under the same geographical projection. It is implemented via raster resampling to the new grid.
Usage

```r
regrid(x, ...) # non-public

.regrid(grid = NULL, mul = NA, res = NA, resx = NA, resy = NA, setbound = NA,
        columns = NA, rows = NA, dim = NA, bbox = NA, expand = NA,
        minx = NA, miny = NA, maxx = NA, maxy = NA, cut = NA, proj4 = NA, crs = NA,
        border = 0, zero = c("keep", "node", "center"), raster = FALSE, tolerance = NA,
        zoom = NA, verbose = FALSE, ...)
```

Arguments

- **x**: Object of class `ursaRaster`.
- **...**:
  1. Arguments, which are passed to non-public `.regrid` to define parameters of new grid.
  2. Set of arguments, which are recognized via their names (using regular expressions) and classes:
     - `reset(Grid)*`: Logical. Whether new grid will be defined as a sessional parameter? If TRUE then returned raster defines new sessional grid. If FALSE then session grid is not changed. Default is TRUE.
     - `resample` Logical or positive numeric. The range of aggregation in the units of cell area. If 0 or FALSE then "nearest neighbor" value is used. The resample>0 defines the side of rectangular area in proportion to cell size; and aggregation of adjacent cells is weighted in proportion to overlapping parts of cells. Default is 1 (or, equally, TRUE); it means that value of output cell is weighted mean of values of overlapped input cells in proportion of overlapping of output cell by input cells.
     - `cover` Positive numeric in the range [0,1]. The maximal fraction of NA values in adjusted input cells for the rule to write NA value to the output cell. Default is 0.499.
     - `cascade` Logical. Option to get more smooth results. If TRUE and resample>2 then resize function is applied sequentially with argument resample<=2.
     - `verbose*` Logical. Value TRUE may provide some additional information on console. Default is FALSE.
- **grid**: Reference `ursaGrid` or `ursaRaster` object. If missing then reference grid is obtained from sessional grid `session_grid()`.
- **mul**: numeric of length 1. Multiplication for changing image size by means of changing of cell size (1/mul). mul>1 decreases cell size, mul<1 increases cell size.
- **res**: numeric of length 1 or 2. New grid size by horizontal and vertical axes. If length is 1 then the same grid size for both axes.
- **resx**: Positive numeric of length 1. New grid size by horizontal axis.
- **resy**: Positive numeric of length 1. New grid size by vertical axis.
- **setbound**: numeric of length 4. Change units of spatial extension and define new spatial extension (boundary box) in the notation c(minx, miny, maxx, maxy).
columns  Positive integer of length 1. Number of columns/samples in the case of definition of new spatial extension (setbound is non-NA).
rows  Positive integer of length 1. Number of rows/lines in the case of definition of new spatial extension (setbound is non-NA).
dim  Positive integer of length 2. Dimension of raster image in the notation c(rows, columns) (or, c(lines, samples)) in the case of definition of new spatial extension (setbound is non-NA).
bbox numeric of length 4. New spatial extension (boundary box) in the notation c(minx,miny,maxx,maxy) in the same units of existing spatial extension.
minx numeric of length 1. New value for left boundary.
miny numeric of length 1. New value for bottom boundary.
maxx numeric of length 1. New value for right boundary.
maxy numeric of length 1. New value for top boundary.
cut numeric of length 4. Vector (left, bottom, right, top) in CRS units for extent expand.
border numeric of length 1 or 4. If length 4, then vector (bottom, left, top, right) in cells for extent expand. If length <4, then value is repeated for length 4.
proj4 character of length 1. New projection string in the PROJ.4 notation

crs character of length 1. The synonym to proj4.
expand numeric of length 1. Multiplier of boundary box.
raster logical. Should return blank ursaRaster object instead of ursaGrid object? See ‘Value’ section
zero character. Define central cell position relative to zero coordinates. If value is "keep", then central cell position is without changes. If value is "node", then zero coordinates are on the crossing of cell borders. If value is "center", then zero coordinates are in the center of central cell. Currently is not implemented. If grid is consistent, then value "keep" is used, else "node".
tolerance numeric. Threshold for comparison float point numerics. Required for internal check of grid consistence. Default is NA; value .Machine$double.eps multiplied on maximal value of coordinates is used.
zoom numeric. Tweak for simultaneous change of expand and mul: expand=zoom, mul=1/zoom. Default is NA.
verbose Reporting via message about violation and restoration of coordinate grid regularity after non-consistence usage of parameters.

Details
Generally, argument resample sets a rectangular region. The area of this region is in proportion to area of output cell. Argument resample is the value of this proportion. Each cell is interpreted as a set of adjoining rectangular figures. The value of output cells is a weighted mean of that input cells, which fall into rectangular region. The weights are defined as an partial area inside of rectangular region.
Function implements "nearest neighbor" resampling method if argument resample=0 (or, resample=FALSE). If resample=1 (or, resample=TRUE) and both input and output rasters have the same cell size, then resampling method is "bilinear interpolation".

Expand raster x to 3 times with cell repeating: regrid(x, mul=3, resample=FALSE) ## nearest neighbor;
Expand raster x to 3 times with cell aggregation: regrid(x, mul=3, resample=TRUE) ## bilinear interpolation;
Contract raster x to 3 times without cell aggregation: regrid(x, mul=1/3, resample=FALSE) ## nearest neighbor;
Contract raster x to 3 times with cell aggregation: regrid(x, mul=1/3, resample=TRUE) ## weighted mean;
Low-pass filtering by 3 x 3 window size: regrid(x, resample=3*3) ## see focal_mean

However, simple contraction regrid(x, mul=1/2, resample=FALSE) is implemented as contraction with aggregation (regrid(x, mul=1/2, resample=FALSE)), because centers or output cells are located in the nodes (crossing of boundaries of input cells).

It seems that for categorical rasters parameter resample=0 is more suitable, because nearest neighboring does not introduce new values to output raster, excepting coincidence of input cells’ nodes and output cell centers.

Usage of proj4 argument specifies only desirable PROJ.4 string and does not do reprojection.

The violation of grid regularity is due to columns and rows of image should be integer. The restoration of grid regularity is realized by spatial extension (boundary box) expansion.

Value

regrid returns object of class ursaRaster.

Return value of non-public function .regrid depends on logical value of raster argument. If raster=FALSE then .regrid returns new grid without any change of sessional grid. If raster=TRUE then .regrid returns blank image and changes sessional grid.

---

**Description**

rep for object of class ursaRaster creates new ursaRaster objects with repetition of original band sequence.

**Usage**

```r
## S3 method for class 'ursaRaster'
rep(x, ...)
```
Replace

Arguments

- **x**: Object of class ursaRaster
- **...**: Further arguments to be passed to or from other methods. Keywords:
  - **times**: Positive integer. Number of times to repeat each band.
If argument has no name, then `times` is assumed.

Value

Object of class ursaRaster.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

c for ursaRaster.

Examples

```r
session_grid(NULL)
session_grid(regrid(mul=1/4))
a <- ursa_dummy(nband=3)
print(a)
b1 <- rep(a,by=2)
print(b1)
b2 <- rep(a,length=5)
print(b2)
b3 <- rep(a[3],3)
print(b3)
```

---

**Description**

This operator is used to set or replace values in portion of bands or lines in ursaRaster object in memory or data writing to file.

**Usage**

```r
# S3 replacement method for class 'ursaRaster'
x[i, j, ...] <- value
```
Arguments

x  ursaRaster object
i  Integer or character. If integer, then band index, specifying bands to replace. If character, either list of band names or character sting for regular expression to match band index. In the (spatial, temporal) interpretation of ursaRaster object j points to temporal component.
j  Mentioned for consistence with internal generic function [<-.
...
value  ursaRaster object or numeric (scalar, matrix, array). The latter is coerced to internal matrix of $value item of ursaRaster object.

Details

Operator `[<-` is high-level implementation for data writing. If `x$value item is not applicable, then value of ursaRaster is not in memory. In this case the controlled by i and j portion is written to file. If both i and j are missing, then `x[] <-value writes values to file wholly.

It is not implemented the simultaneously writing to file portion of bands and portion of lines.
Files (currently, ENVI Binary) are opened for reading and writing.

Value

If values of ursaRaster object are in memory, then modified ursaRaster object with replaced bands or lines.
If values of ursaRaster object are not applicable, then ursaRaster object as is.

description

Connect sequence of points (locations) by direct lines (tracks)

Usage

segmentize(obj, connect=c("consequent", "united"))

Arguments

obj Simple feature (package sf) or Spatial abstract class (package sp) with POINTS spatial geometry.
connect Structure of output segments; either sequence of single segments ("consequent") or single multi-segment ("united").
Details

Function generates \( n-1 \) segments from \( n \) input points. Data (attribute table) is transferred to output object with excluding of first row.

Value

Simple feature (package \textit{sf}) or Spatial abstract class (package \textit{sp}) with LINestring spatial geometry.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
n <- 15
lon <- rev(sort(runif(n,min=40,max=60)))
lat <- sort(runif(n,min=30,max=50))
pt <- data.frame(lon=lon, lat=lat, value=seq(n))
sp::coordinates(pt) <- c("lon", "lat")
sp::proj4string(pt) <- "+proj=longlat"
ct <- ursa_colortable(colorize(pt$value))
tr <- segmentize(pt)
session_grid(pt, expand=1.1)
compose_open(2)
panel_new()

panel_decor()
panel_new()
panel_plot(tr, col=ct, lwd=3)
panel_decor()
compose_legend(ct)
compose_close()
```

Description

Set of functions to generate regular sequences of bands, x-/y-coordinates and columns/rows.

Usage

```r
## S3 method for class 'ursaRaster'
seq(...)

## S3 method for class 'ursaGrid'
seq(...)```
seq

ursa_seqx(obj)
ursa_seqy(obj)
ursa_seqc(obj)
ursa_seqr(obj)

Arguments

Set of arguments, which are recognized via their names (using regular expressions), position and classes.

. First argument (position 1). Object of classes ursaRaster, ursaGrid.
. Second argument (position >1). One-character name. Valid values are in the list c("z","x","y","c","r","lines","samples"). "c" ("samples") and "r" ("lines") specify to generate cell sequence in the horizontal and vertical directions from bottom-left corner, whereas "z" specifies to generate sequence of bands. x and "y" return cell midpoints in spatial dimension.

obj Object of classes ursaRaster, ursaGrid. Missing obj is allowed; in this case the session grid is considered.

Details

All ordinal sequences (axis is "c","r","z") start from 1L. axis="z" is ignored in the function seq for ursaGrid object. The returned value is 1L. seq(obj) for ursaRaster objects is suitable for using in cycles across bands.

Value

Functions ursa_seqx and seq(obj,"x") return x-coordinates of cell midpoints.
Functions ursa_seqy and seq(obj,"y") return y-coordinates of cell midpoints.
Functions ursa_seqc, seq(obj,"samples") and seq(obj,"c") return sequence of cells in horizontal direction.
Functions ursa_seqr, seq(obj,"lines") and seq(obj,"r") return sequence of cells in vertical direction.
Functions seq(obj) and seq(obj,"z") for ursaRaster object returns sequence of bands.
Function seq(obj) and seq(obj,"z") for ursaGrid object returns 1L.

Author(s)

Examples

session_grid(NULL)
session_grid(regrid(mul=1/16))
print(session_grid())
a <- ursa_dummy(nband=5)
print(a)
print(seq(a))
print(seq(a,"c"))
print(seq(a,"x"))
print(ursa_seqx())

---

**session**

*Get and set sessional parameters for grid, CRS, external software for open PNG files.*

### Description

session_grid without arguments returns current grid properties. session_grid with arguments specifies grid, which is used by functions of this package, e.g., for plotting, for opened and created raster images during current session.

session_pngviewer is used to permit external software to open PNG files.

session_tempdir specifies directory for temporal files in some cases.

session_use_experimental_functions allows to use undocumented (experimental) functions.

Group of functions session_proj4, session_crs, session_cellsiz, session_bbox extracts certain properties of sessional grid.

### Usage

```r
session_grid(obj, ...)
session_proj4()
session_crs()
session_cellsiz
session_bbox()
session_dim()

session_pngviewer(allow = NA)
session_tempdir(dst = character())
session_use_experimental_functions()
```

### Arguments

- **obj**
  - Either missing, or NULL, or file name, or object of class ursaRaster, or object of class ursaGrid, or spatial object (simple features (sf), spatial abstracts (sp)).

- **allow**
  - Logical. If TRUE then it is allowed to use external software for viewing PNG files. NA is interpreted as TRUE in the case of "Rscript" usage, and interpreted as FALSE in the case of interactive session or "R CMD BATCH" usage. Default is NA.

- **dst**
  - Character. Directory name for temporal files. Empty character or non-character is interpreted as getwd() in the case of "Rscript" usage, and interpreted as tempdir() in the case of interactive session or "R CMD BATCH" usage. Default is character() (empty character).

- **...**
  - Optional arguments passing to regrid at first.
Details

session_grid deals with option "ursaSessionGrid": options(ursaSessionGrid=...) or getOption("ursaSessionGrid")

Usage session_grid() without arguments return value of "ursaSessionGrid" option via calling
getOption("ursaSessionGrid"). If is.null(getOption("ursaSessionGrid")) then session_grid() returns default CRS.

Usage session_grid(NULL) resets "ursaSessionGrid" option via calling options(ursaSessionGrid=NULL).

The sequential calling

session_grid(NULL)
session_grid()

returns default CRS. For checking that the option has been reset successfully, use getOption("ursaSessionGrid")
after session_grid(NULL)

session_proj4 and session_crs are synonyms.

Value

Object of class ursaGrid. It is a list. Default values are grid parameters of NSIDC polar stereo gridded data of Northern hemisphere with nominal gridded resolution 25 km (https://nsidc.org/data/polar-stereo/ps_grids.html).

List of 9

$ columns: int 304
$ rows : int 448
$ resx : num 25000
$ resy : num 25000
$ minx : num -3850000
$ maxx : num 3750000
$ miny : num -5350000
$ maxy : num 5850000
$ proj4 : chr "+proj=stere +lat_0=90 +lat_ts=70.0 +lon_0=-45.0 +k=1
+x_0=0.0 +y_0=0.0 +a=6378273.000 +b=6356889.449 +units=m +no_defs"
- attr(*, "class")= chr "ursaGrid"
NULL

session_proj4 and session_crs return item proj4.

session_cellsize returns squared root from multiplication of cell dimension: sqrt(resx*resy).

session_pngviewer returns value of getOption("ursaAllowPngViewer").

session_bbox returns named numeric of length 4: minimal x-coordinate (xmin), minimal y-coordinate (ymin), maximal x-coordinate (xmax), maximal y-coordinate (ymax).

session_dim returns named integer of length 2: number of rows (lines) and number of columns (samples).

session_use_experimental_functions added some non-public functions to current namespaces and returns invisible list of function names.
spatial_engine

Wrapper functions for manipulation with non-raster spatial objects

Description

These wrappers return uniform properties or do similar manipulations for spatial objects of different types: simple features (package sf) and abstract class Spatial (package sp). Appropriate functionality ("engine") of respective packages is used.

Usage

spatial_engine(obj, verbose = FALSE)

spatial_crs(obj, verbose = FALSE)
spatial_proj(obj, verbose = FALSE)
spatial_proj4(obj, verbose = FALSE)

spatial_crs(obj, verbose = FALSE) <- value
spatial_proj(obj, verbose = FALSE) <- value
spatial_proj4(obj, verbose = FALSE) <- value

spatial_bbox(obj, verbose = FALSE)
spatial_bbox(obj, verbose = FALSE) <- value

spatial_data(obj, subset = ".+", drop = NA, verbose = FALSE)
spatial_data(obj, verbose = FALSE) <- value
spatial_engine

spatial_geometry(obj, verbose = FALSE)
spatial_geometry(obj, verbose = FALSE) <- value

spatial_geotype(obj, each = FALSE, verbose = FALSE)
spatial_shape(obj, each = FALSE, verbose = FALSE)

spatial_transform(obj, crs, verbose = FALSE, ...)

spatial_coordinates(obj, verbose = FALSE)
spatial_centroid(obj, verbose = FALSE)

spatial_fields(obj, verbose = FALSE)
spatial_colnames(obj, verbose = FALSE)

spatial_fields(obj, verbose = FALSE) <- value
spatial_colnames(obj, verbose = FALSE) <- value

spatial_area(obj, verbose = FALSE)

spatial_dim(obj, verbose = FALSE)

spatial_count(obj, verbose = FALSE)
spatial_nrow(obj, verbose = FALSE)
spatial_ncol(obj, verbose = FALSE)

spatial_filelist(path = ".", pattern = NA, full.names = TRUE, recursive = FALSE,
                 ignore.case = TRUE)
spatial_dir(path = ".", pattern = NA, full.names = TRUE, recursive = FALSE,
           ignore.case = TRUE)

spatial_basename(fname)
spatial_pattern(fname)

is_spatial(obj, verbose = FALSE)

is_spatial_points(obj, verbose = FALSE)
is_spatial_lines(obj, verbose = FALSE)
is_spatial_polygons(obj, verbose = FALSE)

spatial_intersection(x, y,
        geometry=c("default", "polygons", "lines", "points", "all"),
        verbose = FALSE)
spatial_symdiff(x, y, verbose = FALSE)
spatial_difference(x, y, verbose = FALSE)
spatial_union(x, y, byid=NA, verbose = FALSE)
spatial_buffer(obj, dist = 0, quadsegs = 30L, verbose = FALSE)

spatial_trim(obj)

spatial_valid(obj, each = FALSE, reason = FALSE, verbose = FALSE)

spatial_grid(obj)

spatial_bind(...)

**Arguments**

- **obj**: Simple feature (package sf) or Spatial abstract class (package sp) for all functions, excepting spatial_geometry<-. Data frame for Replace function spatial_geometry<-.
- **x, y**: Objects of simple feature (package sf) class or Spatial abstract class (package sp).
- **crs**: Projection EPSG code or projection PROJ.4 string.
- **subset**: Pattern to field names (colnames) of attribute table (data frame) for subsetting using regular expressions. By default, all fields are selected.
- **drop**: Logical. Dropping column of data frame. If TRUE, then vector of data is returned. If FALSE, then structure of data is kept. Default is NA, which is interpreted as TRUE for single column and as FALSE for multiple columns.
- **value**: Value for property assignment in replacement functions. Either numeric EPSG code or character PROJ.4 string for spatial_crs<- and spatial_proj4<-.
- **path**: See description of argument path in function dir.
- **pattern**: See description of argument pattern in function dir.
- **full.names**: See description of argument full.names in function dir.
- **recursive**: See description of argument recursive in function dir.
- **ignore.case**: See description of argument ignore.case in function dir.
- **quadsegs**: Integer. Number of segments per quadrant (fourth of a circle), for all or per-feature. See description for quadsegs argument of gBuffer and for nQuadSegs argument of st_buffer.
- **dist**: Numeric. Buffer distance for all, or for each of the elements. See description for width argument of gBuffer and for dist argument of st_buffer.
- **byid**: Logical. For spatial_union function. TRUE does unite of each feature; FALSE returns a single feature that is the geometric union of the set of features; default NA is coerced to FALSE for unary operation (missing y) and to TRUE for binary operation.
- **fname**: Character. Filename (source or packed) of spatial data.
- **each**: Logical. Whether result will be returned for each record (TRUE) or generalized (FALSE). Default is FALSE.
geometry Character. Desired output geometry for engine="sf". If "default" then output geometry is defined internally (e.g., "polygons" for polygons intersection). If "all" then no output subsetting. Default is "default".

reason Logical. If TRUE, then the reason for validity ("Valid Geometry") or invalidity is returned. If FALSE, then logical value of validity is returned. Default is FALSE.

verbose Logical. Value TRUE provides information on console. Default is FALSE.

spatial_engine returns package name (character string "sf" or "sp"), which functionality is used for manipulation with spatial object obj.

spatial_crs and spatial_proj4 are synonyms. The Extract functions return projection string in the PROJ.4 notation; the Replace functions change projection property of the object.

spatial_bbox (Extract function) returns numeric vector of length 4 with names "xmin", "ymin", "xmax" and "ymax".

spatial_bbox<- (Replace function) assigns boundary bbox to the object; it is valid only for objects of Spatial abstract class (package sp).

spatial_data (Extract function) returns attribute table only, without geometry. Subsetting fields can be specified by argument subset using regular expressions. If drop=TRUE and selected single column then vector is returned instead of data frame.

spatial_data<- (Replace function) adds spatial data to the object geometry. Source data (if presents) are dropped.

spatial_geometry (Extract function) returns only geometry, which format is depended on class of obj.

spatial_geometry<- (Replace function) addes geometry to the object.

spatial_transform does a transformation of spatial coordinates to the new CRS and returns object of the same class as class of obj.

spatial_geotype and spatial_shape are synonyms; each returns type of spatial data: "POINT", "LINESTRING", "POLYGON", "MULTIPOLYGON", .....

spatial_coordinates returns simplified matrix or list of coordinates of original object.

Extract functions spatial_fields and spatial_columns return column names of spatial attributive table. spatial_columns is synonym to spatial_fields.

Replace functions spatial_fields<- and spatial_columns<- change column names of spatial attributive table. spatial_columns<- is synonym to spatial_fields<-.

spatial_area is valid for polygonal geometry. It returns area of polygons.

spatial_length is valid for linear geometry. It returns length of lines.

spatial_dim gets dimension of spatial coordinates; it returns either 2L (XY) or 3L (XYZ).

spatial_count returns number of items of object geometry.

spatial_nrow and spatial_ncol return number of rows and number of columns of attributive table.
spatial_filelist and its synonym spatial_dir return list of files with file extensions, which
are associated with certain GIS vector formats. The function’s basis is dir.
spatial_basename returns basename (without extension) of file fname of spatial object.
spatial_pattern returns pattern of spatial_basename for using in regular expressions.
is_spatial returns logical value does the object belong to the class of spatial data.
is_spatial_points returns logical value does the object have point geometry.
is_spatial_lines returns logical value does the object have (multi)linestring geometry.
is_spatial_polygons returns logical value does the object have (multi)polygonal geometry.
spatial_intersection returns intersection of two spatial objects.
spatial_difference returns difference of two spatial objects.
spatial_symdifference returns symmetric difference of two spatial objects.
spatial_buffer returns buffered spatial object.
spatial_union returns combined geometry without internal boundaries.
spatial_trim returns spatial object without extra attributes added by ursa package.
spatial_grid generates suitable spatial grid from input vector and returns object of class ursaGrid.
spatial_centroid returns spatial centroid.
spatial_bind returns spatial object concatenated from input spatial objects.

Acknowledgements

The great improvement for development of functions for manipulation with spatial objects has been
reached during work in series of projects (2015-2018) for design of marine protected areas in the
Arctic, which were supported by WWF Russia.

Classes and methods in packages sf and sp help.

Examples

   session_grid(NULL)
   n <- 1e2
   x <- runif(n,min=25,max=65)
   y <- runif(n,min=55,max=65)
   z <- runif(n,min=1,max=10)
   da <- data.frame(x=x,y=y,z=z)
   if (requireNamespace("sp")) {
       da.sp <- da
       sp::coordinates(da.sp) <- ~x+y
       sp::proj4string(da.sp) <- "+init=epsg:4326"
       print(spatial_bbox(da.sp))
   }
spatial_read

Wrapper functions for reading spatial objects.

Description

Read either simple features (package sf) and abstract of class Spatial (package sp) from disk using appropriate functionality ("engine") of respective packages is used.

Usage

spatial_read(dsn, engine = c("native", "sp", "sf", "geojsonsf"))

Arguments

dsn  Character. File name of spatial object (vector GIS).

engine  Character. Functionality of which package is used for reading data. If value is "sf", then package sf is used and simple features are returned. If value is "geojsonsf", GDAL driver is GeoJSON and package geojsonsf can be loaded, then package geojsonsf is used and simple features are returned. If value is "sp", then package rgdal is used and Spatial abstracts (package sp) are returned. If value is "native" then engine selection depends of which namespace has already loaded or has suggested package sf been installed.

Details

Currently, list of arguments of this function is simplified and can be expanded.

Value

Depending of used engine, either simple features (package sf) or Spatial abstracts (sp).

Note

For GeoJSON files in the case engine="geojsonsf" reading is faster and the order of fields can be rearranged.

Nikita Platonov <platonov@sevin.ru>
Spatial Write

Spatial write

Wrapper functions for writing spatial objects.

Description

Write spatial object to disk. If spatial object is Simple Features, then appropriate functions from package sf are used. If spatial object are abstract of class Spatial then appropriate functions from packages sp and rgdal are used.

Usage

spatial_write(obj, fname, layer, driver = NA, compress = "",
              ogr2ogr = nchar(Sys.which("ogr2ogr")) > 0, verbose = FALSE)
Arguments

obj       Spatial object: either Simple Features (sf) or Spatial Abstract (sp). List of spatial objects can be used.
fname     Character. File name with or without extension. If extension is missed, then argument driver must be specified.
layer     Character. Layer name. If missed, then basename of fname is used.
driver    Character. Driver for specification of output file format. Default is NA; value is determined from extension of fname.
compress  Character or logical. Will output file or list of files be packed after writing and what archive format will be used. Available character values are "" (default; no compression), "gz", "gzip", "bz2", "bzip2", "zip", "xz". If logical and TRUE, then "zip" is used for driver "ESRI Shapefile" and "gzip" otherwise. If logical and FALSE, then no compression.
ogr2ogr   Logical. If "ogr2ogr" is found in system path, then GDAL utils are used for speed up and layer merge (if obj is list of spatial objects)
verbose   Logical. Value TRUE provides information on console. Default is FALSE.

Details

Based on sf::st_write and rgdal::writeOGR functions with additonal options: compressing of output file(s), coordinates trasforming (to longitudes and latitudes for driver="GeoJSON"), creating multi-layer destination (for driver="SQLite").

Value

invisible NULL.

y <- runif(n,min=55,max=65)
z <- runif(n,min=1,max=10)
da <- data.frame(x=x,y=y,z=z)
if (requireNamespace("sf",quietly=TRUE)) {
  obj1 <- sf::st_as_sf(da,coords=c("x","y"),crs=4326)
summary

Summary of raster image.

Description

Function summary for ursaRaster object produces summaries for each band.
Function summary for ursaValue object produces summaries for all values of raster image regardless of bands.

Usage

## S3 method for class 'ursaRaster'
summary(object, ...)

## S3 method for class 'ursaNumeric'
summary(object, ...)

## S3 method for class 'ursaCategory'
summary(object, ...)

Arguments

object Object of classes ursaRaster, ursaNumeric, or ursaCategory

... Additional arguments affecting the summary produced.
temporal_interpolate

Details

  summary for ursaRaster object applies summary to each column of two-dimensions value matrix and collating the results.
  summary for ursaValue object drops dimensions and applies summary to a vector.

Value

  summary for ursaRaster object returns value of function summary.matrix.
  summary for ursaValue object returns object of class "summaryDefault".

Author(s)

  Nikita Platonov <platonov@sevin.ru>

See Also

  summary in package base.

Examples

  session_grid(NULL)
  session_grid(regrid(mul=1/4))
  a <- ursa_dummy(nband=3)
  print(summary(a))
  print(summary(ursa_value(a)))
  print(a)

  __temporal_interpolate: Fill gaps across bands using moving mean window__

Description

  temporal_interpolate is applicable for multiband raster image, where bands are regular time-stamps or period. For each cell (local operation of map algebra), NA value is replaced by averaging of two closest values (one value before, one value later) inside of moving window.

Usage

  temporal_interpolate(obj, win = 7, cover = 0, verbose = FALSE)

Arguments

  obj
    Object of class ursaRaster or matrix, where spatial locations are by rows and temporal observations are by columns.

  win
    Positive integer. Size of moving window. Required odd value; otherwise is coerced to the closest odd integer.

  cover
    __Not applicable__. For consistence call with temporal_mean.

  verbose
    Logical. TRUE provides some additional information on console. Default is FALSE.
temporal_mean
Smooth value across bands using moving mean window

Description

temporal_mean is applicable for multiband raster image, where bands are regular timestamps or period. For each cell (local operation of map algebra), the values are averaged using moving window.

Usage

temporal_mean(obj, win = 7, cover = 0, verbose = FALSE)
temporal\_mean

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>obj</td>
<td>Object of class ursaRaster or matrix, where spatial locations are by rows and temporal observations are by columns.</td>
</tr>
<tr>
<td>win</td>
<td>Positive integer. Size of moving window. Required odd value; otherwise is coerced to the closest odd integer.</td>
</tr>
<tr>
<td>cover</td>
<td>Numeric in the interval 0 &lt;= cover &lt;= 1 or positive numeric &gt;1. The required amount of non-NA elements in window to do a filtering. Otherwise, NA value is in output cell. If cover&lt;=1 then amount is relative to window size. Default is 0: NA values are produced only if all elements in window have NA value.</td>
</tr>
<tr>
<td>verbose</td>
<td>Logical. TRUE provides some additional information on console. Default is FALSE.</td>
</tr>
</tbody>
</table>

Details

temporal\_mean is similar to function runmean(x=obj,k=win,endrule=\"mean\") from package caTools.

Value

ursaRaster object, if obj is object of class ursaRaster.
matrix object, if obj is a matrix.

Advanced

temporal\_mean is only smoothing of time-series. For time-series analysis and processing it is suggested to apply lower-level approach.

```r
as.matrix (for ursaRaster object with argument coords=FALSE) or ursa_value return matrix with spatial component by rows and temporal component by columns. It is possible to use apply with argument MARGIN=1 to this matrix. If apply returns matrix Y, then this matrix can be coerced to ursaRaster object by calling as.ursa with argument t(Y).

```r
X <- as.matrix(obj)
Y <- apply(X, 1, function(x) {y <- do_something_return_matrix(x); y})
res <- as.ursa(t(Y))
```

For example, package caTools provides some functions for manipulation with moving window.

**ursa**

*Get and set properties of raster image.*

**Description**

For package description see.

**Usage**

```r
ursa(obj, attr, ...)
ursa(obj, attr, ...) <- value
```

**Arguments**

- **obj** Any numeric structure (scalar, matrix, array) for initializing. Object of class ursaRaster for extracting and assigning properties.
- **attr** Character. Name of property.
- **...** Arguments, which are passed for properties specification.
- **value** Value for property assignment.
Details

Initializing function `ursa` with missing argument `attr` is a wrapper for function `as.ursa`.

**ursaConnection**  
*Connection of raster objects.*

**Description**

Class `ursaConnection` is a part of class `ursaRaster`. It defines storage of raster images and manipulations with reading and writing.

**Usage**

```r
## S3 method for class 'ursaConnection'
```

print(x, 
## S3 method for class 'ursaConnection'
seek(con, where = NA, origin = "start", rw = ", ...

Arguments

x  ursaConnection object in function print.
con  ursaConnection object in function seek.
where  Passed to seek for class connection.
origin  Passed to seek for class connection.
rw  Passed to seek for class connection.
...  print: Further arguments passed to generic functions print and str.
seek: Further arguments passed to function seek for class connection.

Details

ursaConnection get item $con from ursaRaster object.
Functions print and is.con are for developers rather than users.
Non-public function .con.skeleton() is used to generate the blank ursaConnection object. This
approach provides unified sequence of list's items:

Value

ursaConnection is a list. The most of names have a relation to specification of ENVI Header Files.
Items:

driver  Character. Keyword of supported image formats. Allowed "ENVI" or "GDAL".
samples  Integer. Number of image columns (samples)
lines  Integer. Number of image rows (lines)
bands  Integer. Number of image bands (channels, layers)
datatype  Integer. Keyword for data type (4 - 32-bit floating point, 2 - 16-bit signed integer,
etc)
interleave  Character "bsq", "bil", "bip". Data interleave - streams of bytes in storage.
byteorder  Integer, 0 or 1. The order of bytes. byteorder=0 less significant byte first,
byteorder=1 most significant byte first
endian  Character. See \dQuote{endian} argument in readBin and writeBin
swap  Integer 0 or 1. Passed to C-funcions fread and fwrite
signed  Logical. Derived from $datatype
offset  Integer. Header offset in binary file. Default is 0.
wkt  Logical. In ENVI Header files wkt=TRUE forced to use “coordinate system string” field instead of “projection info” field
nodata  Numeric. Replacement NA values in the storage.
mode Character. storage.mode of data
sizeof Integer, positive. Size in bytes for stored values. Extracted from $datatype
indexC Integer vector. Sample indices in spatial cropping.
indexR Integer vector. Line indices in spatial cropping.
indexZ Integer vector. Band indices
posC Integer vector. Sample indices in partial reading.
posR Integer vector. Line indices in partial reading.
posZ Integer vector. Band indices in spatial cropping or partial reading.
fname Character. File name. If driver=ENVI, then full path for ENVI binary file.
connection Character. See connections
compress Signed integer. 0L no compressing, -1L compressed file plus decompressed file, -2L decompressed file, 1L - file will be compressed.
seek Logical. Does connection support seek?
handle connections in fact

Author(s)
Nikita Platonov <platonov@sevin.ru>

ursa(obj,"con")

Examples

session_grid(NULL)
print(methods(class="ursaConnection"))
a <- pixelsize()
write_envi(rep(a,5),"tmp1",compress=FALSE)
## change spatial domain for cropping example
g <- session_grid(regrid(lim=c(-1200000,-1400000,1600000,1800000)))
print(g)
b <- open_envi("tmp1")
d <- b[,30:70]
print(ursa(d[2:3],"con"))
close(b)
envi_remove("tmp1")
ursaGrid

Spatial parameters of raster images.

Description

Class ursaGrid is a part of class ursaRaster. It defines spatial locations of image.

Usage

## S3 method for class 'ursaGrid'
print(x, ...)

## S3 method for class 'ursaGrid'
str(object, ...)

## S3 method for class 'ursaGrid'
dim(x)

## S3 method for class 'ursaGrid'
as.data.frame(x, row.names = NULL, optional = FALSE, ...)

Arguments

x ursaGrid object in functions print, dim and as.data.frame.
object ursaGrid object in function str.
row.names Ignored. Argument, which is passed to generic function as.data.frame.
optional Ignored. Argument, which is passed to generic function as.data.frame.
... Further arguments passed to generic functions as.data.frame, print, and str.

Details

The blank ursaGrid object is generated by calling of ursa_grid() without arguments. These approaches provide unified sequence of list’s items:

List of 9
$ columns: int NA
$ rows : int NA
$ resx : num NA
$ resy : num NA
$ minx : num NA
$ maxx : num NA
$ miny : num NA
$ maxy : num NA
$ proj4 : chr ""
- attr(*, "class")= chr "ursaGrid"
NULL
Value

Object of class ursaGrid is a list with items:

- **columns**: Number of columns (samples)
- **rows**: Number of rows (lines)
- **resx**: Grid cell size by horizontal axis
- **resy**: Grid cell size by vertical axis
- **minx**: Left margin of boundary box
- **maxx**: Right margin of boundary box
- **miny**: Bottom margin of boundary box
- **maxy**: Top margin of boundary box
- **proj4**: PROJ.4 string

Function `dim` for object of class ursaGrid returns named vector of length 2: number of rows ("lines") and number of elements in a row ("samples")

Author(s)

Nikita Platonov <platonov@sevin.ru>

print(is.ursa(g,"grid"))
print(g)
```

---

ursaProgressBar: *Progress bar*

Description

Informative progress bars with displaying elapsed and remained time.
Usage

ursaProgressBar(kind = c("tk", "txt"), title = .argv0(),
                 label = "", min = 0, max = 1, initial = min, width = NA,
                 style = 1, tail = FALSE, silent = FALSE)

setUrsaProgressBar(pb, value, title = NULL, label = NULL)

## S3 method for class 'ursaProgressBar'
close(con, ...)

Arguments

kind Character. Type or progress bar. Valid values are "tk" to display progress bar
in tcl/tk window and "txt" to display progress bar in terminal mode. Default is
"tk".

style See description for the same argument in txtProgressBar.

width See description for the same argument in tkProgressBar.

title, label, min, max, initial, value, pb
See description for the same arguments in tkProgressBar and txtProgressBar.

con, ... See description for the same arguments in close.

tail Logical. Behaviour of progress bar appearing. If TRUE then progress bar will be
used after progress step (e.g., at the end of routine). Default is FALSE (before
progress step).

silent Logical. If TRUE then progress bar will not appeared; it can be useful for condi-
tional scripting. Default is FALSE.

Details

Wrapper to one of txtProgressBar,
tkProgressBar.

Visualization of progress bar is updates each 0.5 seconds, it is effective for multiple short-term
iterations.

Progress bars should be closed by calling of appropriate method of generic function close depend-
ing of class of reference progress bar.

Value

ursaProgressBar returns object of reference progress bar.

Note

Function name in style camelCase for consistence with other progress bar functions in R.

Examples

```r
session_grid(NULL)
n1 <- 3
n2 <- 83
p <- 0.0011
#require(tcltk)
pb <- ursaProgressBar(min=0,max=n1,title="first",tail=TRUE)
for (i in seq(n1)) {
  pb2 <- ursaProgressBar(min=0,max=n2,title="second")
  for (i in seq(n2)) {
    setUrsaProgressBar(pb2)
    Sys.sleep(p)
  }
  close(pb2)
  setUrsaProgressBar(pb)
}
close(pb)
```

---

`ursaRaster`  

**Definition of ursaRaster class.**

Description

`ursaRaster` is S3 class for manipulation with georeferenced raster images. See ‘Value’ section.  
is.ursa checks inhering to class `ursaRaster`

Usage

```r
## S3 method for class 'ursaRaster'
print(x, digits = NA, grid = FALSE, raw = FALSE, caption = FALSE, ...)

## S3 method for class 'ursaRaster'
str(object,...)

is.ursa(obj, ref = NULL)
is_ursa(obj, ref = NULL)
```
Arguments

x, object: ursaRaster object.
obj: Any.
digits: Passed to format function.
grid: Logical. If grid=TRUE then returns simplified metadata.
raw: Logical. If FALSE and values are categories, then attempting to restore numeric values from categorical names is before calculating of statistics. If TRUE then values for statistics are used as is. Default is FALSE.
caption: Logical of character. Print title or other identificational info. If logical and TRUE then print variable name or character representation of expression. If non-zero length character, then print this value. If FALSE (default) or zero-length character, then no header for printing.
...: Passed to format function.
ref: Character or NULL. If character, then checking of ursaRaster sub-class(es):

<table>

<td>ursaCategory</td>
</tr>
</tbody>
</table>

Details

is.ursa() is designed mainly for developers to check arguments’ class in function’s call. is_ursa is a synonym to is.ursa.
Stucture of ursaRaster class is generated by non-public .raster.skeleton() function.

Value

ursaRaster is R’s S3 class. It is a list with items:

grid: Geospatial properties. ursaGrid object
con: Connection properties.ursaConnection object
value: 2-dimensional numerical or integer matrix of classes ursaValue in (spatial, temporal) specification formed from (samples*lines, bands). If data are not in memory, then NA.
dim: Dimension of $value. If bands are interpreted as observations in time, then it is spatial by temporal dimension of data. Even data are not in memory, dim is a dimension of whole data.
name: Band names
colortable Color table. ursaColorTable object

is.ursa(x) returns TRUE, if class of x is ursaRaster

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)
print(methods(class="ursaRaster"))

a <- pixelsize()
prefix(a)
prefix(a,grid=TRUE)
s <- substr(as.character(sessionInfo()),1,48)
b <- rep(a,length(s))
bandname(b) <- s
print(b)

require(datasets)
data(volcano)
print(is.ursa(a))
print(is.ursa(volcano))
print(is.ursa(as.ursa(volcano)))

ursaStack List of raster images.

Description

Functions to create list (layers) of multiband raster images (stack in the notation of raster package) and to coerce list of images to single multiband image (brick in the notation of raster package).

Usage

ursa_stack(...) ursa_brick(obj)
ursa_apply(obj, FUN, ...)

## S3 method for class 'ursaRaster'
as.list(x, ...)

## S3 method for class 'ursaStack'
unlist(x, recursive, use.names)
Arguments

**obj, x**  
Object of class `ursaRaster` or list of `ursaRaster` objects. In function `ursa_apply` argument "X", which is passed to function `lapply`.

**FUN**  
Argument "FUN", which is passed to function `lapply`.

**recursive**  
Not used. For consistency with generic function `unlist`.

**use.names**  
Not used. For consistency with generic function `unlist`.

...  
Depending of functions:

- `ursa_stack`, `as.list`  
  List of `ursaRaster` objects

- `ursa_apply`  
  Arguments "...", which are passed to function `lapply`.

Details

`as.list` (of `ursaRaster` object(s)), `ursa_stack` create list of `ursaRaster` objects, where items of list are single-band images. If `x` is `ursaRaster` object, then `list(x)` create a list of length one, which item is multiband image.

`unlist` (for list of `ursaRaster` objects), `ursa_brick` create single multiband `ursaRaster` object. There is an alternative way for unlisting the list of `ursaRaster`: `as.ursa`.

Raster stack is a way to group bands, for example, by units (degree Celsius, meters). Raster brick is a way to combine versatile images to the single multiband image, for example, for saving in file.

Value

- `ursa_stack`, `as.list` return object of class `ursaStack`. It is a list, with class "`ursaStack" attribute.
- `unlist` (for list of `ursaRaster` objects), `ursa_brick` return object of class `ursaRaster`.
- `ursa_apply` returns object of class `ursaStack`, if result is list of `ursaRaster` objects, otherwise returns general `list`.

Warning

There is no any verifications, that grids of `ursaRaster` objects are the same.

Note

Generic `unlist(x)` deals only with class of `x`, but doesn’t take into account class of objects in list (e.g., `x[[1]]`). So, there is no effective way to use only `list/unlist` for `ursaRaster` objects to do a conversion between raster brick and stack. Generic `unlist(x)` deals only with class of `x`, but doesn’t take into account class of objects in list (e.g., `x[[1]]`). So, there is no effective way to use only `list/unlist` for `ursaRaster` objects to do a conversion between raster brick and stack.

lapply list unlist
c for ursaRaster objects.

Examples

```r
session_grid(NULL)
a <- ursa_dummy(3)
print(a)
b1 <- ursa_stack(a[1:2],colorize(a[3],ramp=FALSE))
print(b1)
b2 <- as.list(a)
print(b2)
b3 <- list(a[1],a[2:3])
print(b3)
b31 <- lapply(b3,colorize,ramp=FALSE)
print(b31)
b32 <- ursa_apply(b3,colorize,ramp=FALSE,rev=TRUE)
print(b32)
s311 <- ursa_apply(b31,ursa_colortable)
print(s311)
s21 <- lapply(b2,global_mean)
print(s21)
s22 <- sapply(b2,global_mean)
print(s22)
s31 <- lapply(b3,global_mean)
print(s31)
s32 <- sapply(b3,global_mean)
print(s32)
c1 <- unlist(b1)
print(c1)
c2 <- unlist(b2)
print(c2)
c3 <- unlist(b3)
print(if (is.ursa(c3)) c3 else "broken object")
d3 <- as.ursa(b3)
print(if (is.ursa(d3)) d3 else "broken object")
```

<table>
<thead>
<tr>
<th>ursaValue</th>
<th>Values of raster images.</th>
</tr>
</thead>
</table>

Description

Class ursaValue is a part of class ursaRaster. It contains values of image. In the case of numeric values, the exterior class is ursaNumeric. In the case of categorical values, the exterior class is ursaCategory.
## ursaValue

### Usage

```r
## S3 method for class 'ursaCategory'
print(x, ...)

## S3 method for class 'ursaNumeric'
print(x, ...)

ursa_value(obj, band)
ursa_value(obj, band) <- value
```

### Arguments

- **x**  
  Object of the one of classes ursaNumeric or ursaCategory

- **...**  
  Further arguments passed to generic functions `print` and `str`.

- **obj**  
  Object of class ursaRaster

- **band**  
  Optional. Vector of band numbers (positive integer) or band names (character).

- **value**  
  Numeric or integer scalar, vector, or matrix. Coerced to dimension of ursaValue.

### Details

Try to use high-level assignment using replacement `[<`- operator for class ursaRaster. However, if you don’t get desired result, you can downgrade the level of your code.

### Value

Object of class ursaNumeric is a numerical matrix. Object of class ursaCategory is an integer matrix. Dimensions of this matrix:

- `dim(...)[1]`  
  Spatial domain; the length is multiplications of lines (rows) and samples (columns)

- `dim(...)[2]`  
  Band or temporal domain; the length is number of bands

It is allowed to use scalar value `NA` in the case when values are not in memory. In this case the class is ursaValue.

### Author(s)

Nikita Platonov <platonov@sevin.ru>

- Extract `[` and replacement `[<`- methods for class ursaRaster

Examples

```r
session_grid(NULL)
session_grid(regrid(mul=1/4))
a1 <- create_envi("exam1.envi", bandname=c("today","tomorrow"))
str(ursa_value(a1))
close(a1)
envi_remove("exam1")
a2 <- ursa_dummy(nband=4, min=1, max=99)
str(ursa_value(a2), digits=3)
a3 <- as.integer(a2)
str(ursa_value(a3))
str(ursa_value(a3,2))
print(ursa_value(a3))
print(a3)
ursa_value(a3,"Band 2") <- 199
ursa_value(a3)[,3] <- 299
a3[4] <- 399
print(a3)
ursa_value(a3[1:3]) <- ursa_value(a3[4])
print(a3)
ursa_value(a3[1:3]) <- -c(1:3)
print(a3)
```

ursa_cache

Cache management of ursa package

Description

This help topic is about how cache is managed in the package.

Usage

```r
ursa_cache()
```

Details

Users, who want to keep cache files between R sessions, should define option with name ursaCacheDir and value of the path for storage of cache files. This setting can be specified if ~/.Rprofile file, or be in your code. If you specify permanent cache directory as sub-directory of tempdir() (see example), it will be removed after finishing of R session.

Value

NULL

Note

There is no neccessary to call this function. It just defines this help topic.
**ursa_crop**

**Author(s)**

Nikita Platonov <platonov@sevin.ru>

**Examples**

```r
## internet connection is required
options(ursaCacheDir=file.path(tempdir(),".ursaCacheDir"))
print(c(tempdir=tempdir(),ursaCacheDir=getOption("ursaCacheDir")))
glance("Mount Eden",place="park")
dir(getOption("ursaCacheDir"))
```

**Description**

Function ursa_crop

makes such spatial subset of source raster image, where margins of ‘no data’ values are absent or have specified width.

**Usage**

```r
ursa_crop(obj, condition, border = 0, resetGrid = TRUE, verbose = FALSE)
```

**Arguments**

- **obj** Object of class ursaRaster
- **condition** Object of class ursaRaster or missing. The condition for cutting. If ‘missing’ then condition is defined from obj.
- **border** Integer of length 1 or 4. Desired margins for geographical subset. Units are cells (pixels).
- **resetGrid** Logical. If resetGrid=TRUE then sessional grid parameters is established from grid parameters of created raster. If resetGrid=FALSE then sessional grid parameters keep without change. Default is TRUE.
- **verbose** Logical. TRUE provides some additional information on console.

**Details**

This function calls regrid with passing values of arguments resetGrid and verbose without changes.

This function is an instrument for data compression for spatial matrices with wide margins of ‘no data’ value. It keeps spatial structure (pixel’s neighborhood) in the internal data storage. Otherwise, compress reduces object size using spatial indexing with dropping of spatial structure.
Value

Object of class ursaRaster

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
'printCR' <- function(obj) print(with(ursa_grid(obj),c(c=columns,r=rows)))
g0 <- session_grid()
a <- pixelsize()
 th <- with(ursa_grid(a),resx*resy*1e-6)
a0 <- a[a>th*0.9]
print(session_grid())
printCR(a0)
print(a0)
a1 <- ursa_crop(a0,resetGrid=TRUE)
print(session_grid())
printCR(a1)
print(a1)
a2 <- ursa_crop(a0,resetGrid=FALSE)
print(session_grid())
printCR(a2)
print(a2)
a3 <- a[a>=(th*0.85 & a<=(th*1.01)]
b1 <- ursa_dummy(nband=3,min=0,max=255)
print(b1)
b2 <- ursa_crop(b1[a3>0],border=10)
print(b2)
printCR(b2)
b2[is.na(b2)] <- 255
display_rgb(b2)
b3 <- ursa_crop(b1,a3,border=0)
print(b3)
printCR(b3)
```
Arguments

obj ursaRaster object. It is allowed ursaGrid object for ursa_proj (Extract) function.

keepGrid Logical. Should sessional grid be changed after assignment. Default is FALSE.

value Character sting in PROJ.4 format.

Details

Both Extract and Replace functions ursa_proj() and ursa_proj4() are synonyms for ursa_crs.

Value

Extract function ursa_crs returns character value of $grid$crs item of ursaRaster object.

Replace function ursa_crs<- returns ursaRaster with modified $grid$crs item.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
a <- ursa_dummy(nband=1)
print(ursa_crs(a))
p4s <- "+init=epsg:3576"
ursa_crs(a) <- p4s
print(ursa_crs(a))
fname <- tempfile()
write_envi(a,fname)
a2 <- read_envi(fname,resetGrid=TRUE)
print(ursa_crs(a2))
try(print(rgdal::CRSargs(sp::CRS(p4s))))
envi_remove(fname)
```

rsa_dummy

Generate raster image for examples.

Description

ursa_dummy returns georeferenced raster image with required number of bands. The value of such image has no sense in reality, but are suitable for R's examples.

Usage

```r
ursa_dummy(nband = 3L, minvalue = 0, maxvalue = 255, mul = 1, elements = 8L, bandname = NULL, nodata = TRUE, resetGrid=FALSE)
```
Arguments

- **nbond**: Positive integer. Number of bands. Default is 3L.
- **minvalue**: Numeric of length 1. Minimal value for raster image. Default is 0.
- **maxvalue**: Numeric of length 1. Maximal value for raster image. Default is 255.
- **mul**: Positive numeric. The scaling of the existing session grid. Value 1 means the actual pixel size. Value <1 decreases image size by increasing cell size. Value >1 decreases image size by increasing cell size. Default is 1.
- **elements**: Positive integer. Maximal dimension of matrix, which is proportional to session grid. If elements has small value then the resulting image is smooth, like low-resolution image. The elements has big value, then the resulting image is like white noise.
- **bandname**: Character vector or NULL. Band names for created raster image. If NULL, then band names are generated automatically. Default is NULL.
- **nodata**: Numerical or logical. Set value, which is interpreted as 'no-data' flag. If logical and FALSE then no no-data flag is assigned. If logical and TRUE then value of no-data flag is generated automatically. If numeric, then no-data is assigned to value of this argument. Default is TRUE.
- **resetGrid**: Logical. Whether the grid will be reset to default before raster generation? If FALSE then raster is generated in the sessional grid. If TRUE then default parameters are used for raster and session. Default is FALSE.

Details

Currently, the values are generated using `runif`.
The value `mul<1` speeds up raster generation.

Value

Object of class ursaRaster

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
a1 <- as.integer(ursa_dummy(nband=1,mul=1/16,elements=1e3)) ## white noise
display(a1,legend=NULL)
a2 <- ursa_dummy()
print(a2)
display_brick(a2,decor=FALSE)
display_stack(a2,decor=FALSE)
display_rgb(a2,decor=FALSE)
```
**ursa_grid**  

*Extract and assign spatial parameters of raster images.*

**Description**

Raster image (ursaRaster) contains embedded spatial parameters (ursaGrid) in item $grid$. These functions manipulate with item $grid$.

**Usage**

```r
ursa_grid(obj)
ursa_grid(obj) <- value

ursa_ncol(obj)  
ursa_nrow(obj)  
ursa_columns(obj)  
ursa_rows(obj)  
ursa_samples(obj)  
ursa_lines(obj)  

ursa_extent(obj)  
ursa_bbox(obj)  

consistent_grid(obj, ref, expand = 1, border = rep(0, 4), verbose = FALSE)
```

**Arguments**

- **obj**: ursaRaster object. For ursa_grid function list of ursaRaster objects is allowed.
- **value**: ursaGrid object.
- **ref**: ursaGrid reference object.
- **expand**: Positive numeric. Multiplier of boundary box.
- **border**: integer of length 1 or 4. If length 4, then vector (bottom, left, top, right) in cells for extent expand. If length <4, then value is repeated for length 4. Passed to regrid().
- **verbose**: Logical. Some output in console. Primarily for debug purposes.

**Details**

**ursa_grid**- may used to minor corrections of spatial parameters. However, it seems that this function is not claimed in practice.

**ursa_ncol**, **ursa_columns**, **ursa_samples** are synonyms for extracting number of columns/samples.

**ursa_nrow**, **ursa_rows**, **ursa_lines** are synonyms for extracting number of rows/lines.

**ursa_extent**, **ursa_bbox**, are synonyms for extracting boundary box (spatial extent).

**consistent_grid** transforms dimension (ursa_nrow) by ursa_ncol() obj-grid to dimension of ref-grid. This helpful for multipanel plotting if objects have different boundary boxes.
Value

ursa_grid return value of $grid item of ursaRaster object.

ursa_grid<- return ursaRaster with modified $grid item.

ursa_ncol, ursa_columns, ursa_samples return integer of length 1.

ursa_nrow, ursa_rows, ursa_lines return integer of length 1.

ursa_extent, ursa_bbox return numeric of length 4 (xmin, ymin, xmax, ymax).

ursa_consistent returns ursaGrid object.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

session_grid(NULL)
a <- pixelsize()
print(ursa_grid(a))
ursa_grid(a)$crs <- gsub("\".0+","",ursa_grid(a)$crs)
print(ursa_grid(a))

Description

Function shows information about raster CRS, data type, storage mode, nodata value, structure of band names.

Usage

ursa_info(obj, detail = NA, ...)

Arguments

obj ursaRaster object
detail Not used. Reserved for potential detail levels
...
Arguments, which are passed to str.

Details

ursa_info generates a list and then shows structure of this list via function str.
Value

Object of *temporal* class `ursaMetadata` is a list with items:

- **columns**: Number of columns (samples)
- **rows**: Number of rows (lines)
- **resx**: Grid cell size by horizontal axis
- **resy**: Grid cell size by vertical axis
- **minx**: Left margin of boundary box
- **maxx**: Right margin of boundary box
- **miny**: Bottom margin of boundary box
- **maxy**: Top margin of boundary box
- **proj4**: PROJ.4 string
- **nodata**: Optional. Value, which is interpreted as NA
- **datatype**: Optional. If data are on disk, then integer code of data type.
- **interleave**: Optional. If data are on disk, then abbreviation of bands interleave.
- **mode**: Character of length 2: *storage mode* and *class* of value. If data has not been read, then class is "logical". If data is not in memory, then storage mode is "raw".
- **bandname**: Band names.
- **colortable**: Optional. Structure of *color table*.

Function returns NULL.

`str`  
`print.ursaRaster`

Examples

```r
session_grid(NULL)
a <- as.integer(round(ursa_dummy(nband=3)))

print(a) # print data
ursa_info(a,digits=1) # print metadata

fname <- tempfile()
write_envi(a,fname,compress=FALSE)
b1 <- open_envi(fname)
ursa_info(b1)
close(b1)
b2 <- read_envi(fname)
```
ursa_info(b2)

# print ENVI header
sapply(c(" -------------- begin --------------",readLines(paste0(fname,".hdr"))," --------------- end ---------------"),message)
envi_remove(fname)

ursa_new

Create raster image in memory

Description

`ursa_new` creates object of class `ursaRaster` in memory using session grid parameters or properties of input object (matrix or array). By option, band names and ignore values are specified.

Usage

`ursa_new(...)`

Arguments

Set of arguments, which are recognized via their names (using regular expressions) and classes:

- **value** Pattern is `"(^value)"`. Admissible classes are (matrix, array, numeric, logical). Values to fill image. Array or matrix defines raster grid. If value=FALSE (logical), then created raster image has no values. By default, value=NA, the created raster image is filled by blank values (NA).
- **nbands** Positive integer. Number of bands. Default is 1L.
- **bandname** Character. Band names. Default is NULL. If specified, then nbands is ignored, and the number of bands is equal to length of bandname character vector.
- **ignorevalue** Integer or numeric. Value in ENVI binary file, which is interpreted as NA in R.
- **datatype** Positive integer c(1L, 2L, 3L, 4L, 5L, 11L, 12L, 13L) or character. Data type (integer, floating-point) and byte length. See details for argument datatype of function `create_envi`. Required for writing raster to ENVI binary file. Optional for rasters in memory. Default is NA: data type is defined internally.
- **colortable** Object of class `ursaColorTable`. Color table for raster. Default is NULL: color table is absent.
- **permute** Logical. Should dimensions of input matrix be changed. Default is FALSE.
- **flip** Logical. Vertical flip for input matrix. Default is FALSE: no flip.
- **crs** Character or object of class `ursaGrid`. The reference grid for raster's cells. Default is NULL: the grid is defined either from matrix/array structure or from sessional parameters.
verb(ose) Logical. Value TRUE may provide some additional information on console. Default is FALSE.

Details

`ursa_new` creates `ursaRaster` object in memory. To manipulate with raster chunks use the followed construction:

```r
a <- create_envi(fname,...)
a[condition_1] <- value
print(a[condition_2])
...
close(a)
```

`ursa_new` is designed to create blank raster images. Use `as.ursa` for conversion R objects to `ursaRaster`.

Value

Object of class `ursaRaster`.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

`as.ursa`, `create_envi`.

Examples

```r
session_grid(NULL)
a1 <- ursa_new(volcano)
print(a1)
display(a1)

a2 <- ursa_new(volcano,flip=TRUE)
print(a2)
display(a2)

a3 <- ursa_new(volcano,permute=TRUE)
print(a3)
display(a3)

dima <- c(200,300,4)
b1 <- as.ursa(array(runif(prod(dima)),dim=dima))
print(b1)
display_brick(b1,scale=1,palname="Greys",decor=FALSE)

session_grid(NULL)
```
write_envi <- ursa_new(seq(3))
print(c1)
c2 <- ursa_new(seq(3),bands=3)
print(c2)
c3 <- ursa_new(value=FALSE)
str(ursa_value(c3))
c4 <- ursa_new(bands=2,nodata=-99L)
print(c4)
print(ignorevalue(c4))
c5 <- ursa_new(bandname=format(Sys.Date()+seq(7)-1,"%A"))
ursa_value(c5) <- rev(seq(nband(c5)))
c5 <- colorize(c5)
c6 <- ursa_colortable(c5)
print(c5)

v <- ursa_value(c5[3:5])
str(v)
v <- c(v)
str(v)
c6 <- ursa_new(v,colortable=ct)
print(c6)
print(ursa_colortable(c6))

write_envi <- Write raster image to ENVI .hdr Labelled Raster file.

Description

write_envi writes in-memory object of class ursaRaster to disk in the ENVI .hdr Labelled Raster file format.

Usage

write_envi(obj, ...)

Arguments

obj Object of class ursaRaster.
...
Arguments, which are passed to create_envi. Usually, only file name (character) is required. If missing, then occasional name is assigned.

Details

write_envi implements writing the whole ursaRaster object to disk. For multiple access to disk (by chunks), use followed construction:
write_envi

a <- create_envi(fname)
a[condition_1] <- value1
a[condition_2] <- value2
...
close(a)

Value

Integer code of ENVI data type. See values of the “data type” field in description of the ENVI Header Format.

Author(s)

Nikita Platonov <platonov@sevin.ru>

See Also

create_envi, Replace method [<- for ursaRaster object, close_envi (close for ursaRaster object).

write_gdal(..., driver="ENVI") uses GDAL (rgdal) for writing ursaRaster object to the ENVI .hdr Labelled Raster file.

Examples

session_grid(NULL)

write_gdal  

*Write raster image to GDAL file(s)*

**Description**

`write_gdal` writes in-memory object of class `ursaRaster` to disk using GDAL from `rgdal` package.

**Usage**

```
write_gdal(obj, ...)  
ursa_write(obj, fname)
```

**Arguments**

obj  
Object of class `ursaRaster`.

...  
Arguments, which are passed to `create_gdal`. Usually, only file name with extension (character) is required. If extension is ".envi", then GDAL driver "ENVI" is used. If extension is ".tif", then GDAL driver "GTiff" is used. If extension is ".img", then GDAL driver "HFA" is used. If extension is ".jpg" or "*.jpeg", then GDAL driver "JPEG" is used. If extension is ".bmp", then GDAL driver "BMP" is used. If extension is ".png", then GDAL driver "PNG" is used. Additionally, argument `driver` should be specified. If argument `...` is missing, then occasional name is assigned.

fname  
Character. File name with extension.

**Details**

`ursa_write` is simplified call of `write_gdal`.

`write_gdal` implements writing the whole `ursaRaster` object to disk. For multiple access to disk (by chunks), use followed `Replace` construction:

```
a <- create_gdal(fname)
a[condition_1] <- value1
a[condition_2] <- value2
...
close(a)
```

**Value**

Integer code of ENVI data type. See values of the “data type” field in description of the ENVI Header Format.

**Author(s)**

Nikita Platonov <platonov@sevin.ru>
zonal_stat

Zonal statistics for raster maps

Description

'Zonal' operator of map algebra. Applied to raster images.

Usage

zonal_stat(x, by, FUN, table = FALSE)

## S3 method for class 'ursaRaster'
aggregate(x, by, FUN, table = FALSE, ...)

Arguments

x ursaRaster object. Image for analysis.
by ursaRaster object. Image of grouping elements.
FUN a function to compute the summary statistics which can be applied to all data subsets.
table Logical. If table=TRUE then summary statistics for each group is returned. The statistics is defined by FUN. If stat=FALSE then result is presented as ursaRaster object.
... Other arguments which passed to function aggregate of package stats
Details

`zonal_stat` is a wrapper of `aggregate(x, by, FUN, table=FALSE, na.rm=TRUE)`

You can use multichannel image (argument `x`) for analysis.

You can use multichannel raster image for group elements (argument `by`)

Value

If `table=FALSE` then `ursaRaster` object of summarized statistics.
If `table=TRUE` then `data.frame`.

Author(s)

Nikita Platonov <platonov@sevin.ru>

Examples

```r
session_grid(NULL)
session_grid(regrid(mul=1/2))
a <- pixelsize()
val <- c(normal=a, half=a/2)
gr <- c(group=colorize(a, nbreak=1))
print(as.table(gr))
## display(gr)
ra <- round(aggregate(val, gr, mean), 4)
print(ra)
print(as.table(ra[1]))
print(as.table(ra[2]))
da <- aggregate(val, gr, table=TRUE, mean)
n <- aggregate(a, gr, table=TRUE, length)[, 2, drop=FALSE]
da <- cbind(da, n=unname(n))
gr2 <- c(group2=colorize(a, nbreak=6))
mgr <- list(gr, gr2)
da2 <- aggregate(val[1], mgr, table=TRUE, mean)
print(da2)
da3 <- aggregate(val, mgr, table=TRUE, mean)
print(da3)
ra3 <- aggregate(val, mgr, table=FALSE, mean) ### not implemented for rasters
print(ra3)
```
