

# Package ‘widals’

February 20, 2015

**Type** Package

**Title** Weighting by Inverse Distance with Adaptive Least Squares for  
Massive Space-Time Data

**Version** 0.5.4

**Date** 2014-03-02

**Author** Dave Zes

**Maintainer** Dave Zes <zesdave@gmail.com>

**Description** Fit, forecast, predict massive spacio-temporal data

**Depends** snowfall

**Suggests** SSsimple

**License** GPL (>= 2)

**LazyLoad** yes

**Repository** CRAN

**NeedsCompilation** yes

**Date/Publication** 2014-03-03 07:42:17

widals-package	<i>Weighting by Inverse Distance with Adaptive Least Squares for Massive Space-Time Data</i>
----------------	--

---

## Description

Fit, forecast, predict massive spacio-temporal data

## Details

Package: widals  
 Type: Package  
 Version: 0.5.4  
 Date: 2014-03-02  
 License: GPL (>=2)

The two essential functions are [widals.snow](#) and [widals.predict](#), both contain an Adaptive Least Squares (ALS) prediction stage and complementary 'stochastic adjustment' stage. The function [H.als.b](#) solely fits with ALS.

This package offers the user a metaheuristic stochastic search to locate the scalar WIDALS hyperparameters. The function [MSS.snow](#) along with helper functions [fun.load](#) serve this end. In fairness, providing some useful amount of generality makes this aspect of `widals` a bit challenging to learn. The user new to this package should expect to spend a couple hours playing with the examples before effectively applying these functions to their own data.

---

`applystnd.Hs`*Standardize Spacial Covariates with Existing Object*

---

**Description**

Standardize spacial covariates with respect to both the space and time dimensions

**Usage**`applystnd.Hs(Hs0, x)`**Arguments**

`Hs0` Spacial covariates (of interpolation sites). An  $n^* \times p_s$  numeric matrix.  
`x` Spacial standardization object, as created by [stnd.Hs](#).

**Value**An  $n^* \times p_s$  matrix.**See Also**[stnd.Hst.ls](#), [applystnd.Hst.ls](#).**Examples**

```
n.all <- 21
Hs.all <- cbind(1, rnorm(n.all, 1, 0.1), rnorm(n.all, -200, 21))

ndx.interp <- c(1,3,5)
ndx.support <- I(1:n.all)[ -ndx.interp ]

Hs <- Hs.all[ndx.support, , drop=FALSE]

xsns.obj <- stnd.Hs(Hs)

Hs0 <- Hs.all[ndx.interp, , drop=FALSE]
```

```

sHs0 <- applystnd.Hs(Hs0, xsns.obj)
sHs0

xsns.obj$sHs

crossprod(xsns.obj$sHs) / nrow(Hs)

crossprod(sHs0) / nrow(sHs0)

## The function is currently defined as
function (Hs0, x)
{
  sHs0 <- t((t(Hs0) - x$h.mean)/x$h.sd)
  if (x$intercept) {
    sHs0[, 1] <- 1/sqrt(x$n)
  }
  return(sHs0)
}

```

---

 applystnd.Hst.ls

*Standardize Space-Time Covariates with Existing Object*

---

### Description

Standardize spacio-temporal covariates with respect to both the space and time dimensions

### Usage

```
applystnd.Hst.ls(Hst0.ls, x)
```

### Arguments

Hst0.ls	Space-time covariates (of interpolation sites). A list of length $\tau$ , each element should be a $n^* \times p_{st}$ numeric matrix.
x	Space-time standardization object, as created by <a href="#">stnd.Hst.ls</a> .

### Value

An unnamed list of length  $\tau$ , each element a  $n^* \times p_{st}$  numeric matrix.

### Examples

```

tau <- 20
n.all <- 10

Hst.ls.all <- list()
for(tt in 1:tau) {

```

```

Hst.ls.all[[tt]] <- cbind(rnorm(n.all, 1, 0.1), rnorm(n.all, -200, 21))
}

ndx.interp <- c(1,3,5)
ndx.support <- I(1:n.all)[ -ndx.interp ]

Hst.ls <- subsetsites.Hst.ls(Hst.ls.all, ndx.support)

xsnst.obj <- stnd.Hst.ls(Hst.ls)

Hst0.ls <- subsetsites.Hst.ls(Hst.ls.all, ndx.interp)

sHst0.ls <- applystnd.Hst.ls(Hst0.ls, xsnst.obj)

Hst.sumup(xsnst.obj$sHst.ls)

Hst.sumup(sHst0.ls)

## The function is currently defined as
function (Hst0.ls, x)
{
  tau <- length(Hst0.ls)
  sHst0.ls <- list()
  for (i in 1:tau) {
    sHst0.ls[[i]] <- t((t(Hst0.ls[[i]]) - x$h.mean)/x$h.sd)
  }
  return(sHst0.ls)
}

```

---

create.rm.ndx.ls      *Cross-Validation Indices*

---

### Description

Create a list of vectors of indices to remove for  $k$ -fold cross-validation

### Usage

```
create.rm.ndx.ls(n, xincmnt = 10)
```

### Arguments

n	Number of sites. A scalar integer.
xincmnt	How many cv folds, i.e., $k$ .

## Details

The name of the object produced by this function is commonly `rm.ndx` in this documentation. See [MSS.snow](#) for a reminder that this object is passed out-of-scope when using `MSS.snow`.

In this package `rm.ndx` is used by [Hals.fastcv.snow](#) and [widals.snow](#); however, creating this object as a list using this function is only necessary when using [widals.snow](#) with `cv=2` (i.e., 'true' cross-validation).

## Value

An unnamed list of integer (>0) vectors.

## Examples

```
n <- 100
xincmnt <- 7
rm.ndx <- create.rm.ndx.ls(n=n, xincmnt=xincmnt)
rm.ndx

##### if we want randomization of indices:
n <- 100
xincmnt <- 7
rm.ndx <- create.rm.ndx.ls(n=n, xincmnt=xincmnt)

rnd.ndx <- sample(I(1:n))
for(i in 1:length(rm.ndx)) { rm.ndx[[i]] <- rnd.ndx[rm.ndx[[i]]] }
rm.ndx

## The function is currently defined as
function (n, xincmnt = 10)
{
  rm.ndx.ls <- list()
  for (i in 1:xincmnt) {
    xrm.ndxs <- seq(i, n + xincmnt, by = xincmnt)
    xrm.ndxs <- xrm.ndxs[xrm.ndxs <= n]
    rm.ndx.ls[[i]] <- xrm.ndxs
  }
  return(rm.ndx.ls)
}
```

---

crispify

*Observation-Space Stochastic Correction*

---

## Description

Improve observation-space predictions using 'left over' spacial correlation between model residuals

## Usage

```
crispify(locs1, locs2, Z.delta, z.lags.vec, geodesic, alpha, flatten, self.refs,
lags, std.d = FALSE, log10cutoff = -16)
```

**Arguments**

locs1	Locations of supporting sites. An $n \times 3$ matrix, first column is spacial $x$ , second column is spacial $y$ , third column contains relative temporal 'distance'. If the <code>geodesic</code> is TRUE, make sure latitude is in the first column.
locs2	Locations of interpolation sites. An $n^* \times 3$ matrix, where $n^*$ is the number of interpolation sites. See <code>locs1</code> above.
Z.delta	Observed residuals. A $\tau \times x$ matrix.
z.lags.vec	Temporal lags. An integer vector or scalar.
geodesic	Use geodesic distance? Boolean. If true, distance (used internally) is in units kilometers.
alpha	The WIDALS distance rate hyperparameter. A scalar non-negative number.
flatten	The WIDALS 'flattening' hyperparameter. A scalar non-negative number. Typically between 0 and some number slightly greater than 1. When 0, no crispification.
self.refs	Which sites are self-referencing? An integer vector of (zero-based) lag indices, OR a scalar set to -1. This argument only has meaning when <code>locs1</code> is identical to <code>locs2</code> . If the <code>lags</code> argument is, say, 0, then it would be pointless to smooth predictions with existing values. In this case, we can set <code>self.refs = 0</code> . If <code>locs1</code> is NOT the same as <code>locs2</code> , then set this argument to -1.
lags	Temporal lags. An integer vector or scalar. E.g., if the data's time increment is daily, then <code>lags = c(-1, 0, 1)</code> would have <code>crispify</code> smooth today's predictions using yesterdays, today's, and tomorrow's observed residuals.
stnd.d	Spacial compression. Boolean.
log10cutoff	Weight threshold. A scalar number. A value of, e.g., -10, will instruct <code>crispify</code> to ignore weights less than $10^{(-10)}$ when smoothing.

**Details**

This function is called inside `widals.predict` and `widals.snow`. It may be useful for the user in building their own WIDALS model extensions.

**Value**

A  $\tau \times x$  matrix.

**See Also**

`widals.predict`, `widals.snow`.

**Examples**

```
##### here's an itty-bitty example
##### simulate itty-bitty data
```

```

tau <- 21 ##### number of time points

d.alpha <- 2
R.scale <- 1
sigma2 <- 0.01
F <- 1
Q <- 0

n.all <- 14 ##### number of spacial locations

set.seed(9999)

library(SSsimple)

locs.all <- cbind(runif(n.all, -1, 1), runif(n.all, -1, 1)) ##### random location of sensors
D.mx <- distance(locs.all, locs.all, FALSE) ##### distance matrix

##### create measurement variance using distance and covariogram
R.all <- exp(-d.alpha*D.mx) + diag(sigma2, n.all)

Hs.all <- matrix(1, n.all, 1) ##### constant mean function

##### use SSsimple to simulate system
xsssim <- SS.sim(F=F, H=Hs.all, Q=Q, R=R.all, length.out=tau, beta0=0)
Z.all <- xsssim$Z ##### system observation matrix

##### suppose use the global mean as a prediction

z.mean <- mean(Z.all)

Z.delta <- Z.all - z.mean

z.lags.vec <- rep(0, n.all)

geodesic <- FALSE
alpha <- 5
flatten <- 1

## emulate cross-validation, i.e.,
## don't use observed site values to predict themselves (zero-based)
self.refs <- 0
lags <- 0

locs1 <- cbind(locs.all, rep(0, n.all))
locs2 <- cbind(locs.all, rep(0, n.all))

Z.adj <- crispify(locs1, locs2, Z.delta, z.lags.vec, geodesic, alpha,
  flatten, self.refs, lags, std.d = FALSE, log10cutoff = -16)

Z.adj

```

```

Z.hat <- z.mean + Z.adj

sqrt( mean( (Z.all - Z.hat)^2 ) )

##### set flatten to zero -- this means no crispification

Z.adj <- crispify(locs1, locs2, Z.delta, z.lags.vec, geodesic, alpha,
  flatten=0, self.refs, lags, stnd.d = FALSE, log10cutoff = -16)

Z.adj

Z.hat <- z.mean + Z.adj

sqrt( mean( (Z.all - Z.hat)^2 ) )

## The function is currently defined as

  }
  dim(Z.out) <- c(tau, n1)
  return(Z.out)
}

```

---

 distance

*Spatial Distance*

---

### Description

Calculate spacial distance between two sets of locations (in two-space)

### Usage

```
distance(locs1, locs2, geodesic = FALSE)
```

### Arguments

locs1	First set of locations. E.g., supporting sites: An $n \times 2$ matrix. If geodesic is set to true, make sure to place latitude in first column.
locs2	Second set of locations. E.g., interpolation sites: An $n^* \times 2$ matrix. If geodesic is set to true, make sure to place latitude in first column.
geodesic	Use geodesic distance? Boolean.

### Details

If geodesic is set to FALSE, Euclidean distance is returned; if TRUE, Earth's geodesic distance is returned in units kilometers.

### Value

An  $n \times n^*$  matrix.

### Examples

```

locs1 <- cbind( c(-1, -1, 1, 1), c(-1, 1, -1, 1) )
locs2 <- cbind( c(0), c(0) )

distance(locs1, locs2)

```

```

locs1 <- cbind( c(32, 0), c(-114, -114) )
locs2 <- cbind( c(0), c(0) )

distance(locs1, locs2, TRUE)

##### separation of one deg long at 88 degs lat (near North-Pole) is (appx)
locs1 <- cbind( c(88), c(-114) )
locs2 <- cbind( c(88), c(-115) )
distance(locs1, locs2, TRUE)

##### separation of one deg long at 0 degs lat (Equator) is (appx)
locs1 <- cbind( c(0), c(-114) )
locs2 <- cbind( c(0), c(-115) )
distance(locs1, locs2, TRUE)

## The function is currently defined as
function (locs1, locs2, geodesic = FALSE)
{
  # dyn.load("~/Files/Creations/C/distance.so")
  n1 <- nrow(locs1)
  n2 <- nrow(locs2)
  d.out <- rep(0, n1 * n2)
  if (geodesic) {
    D.Mx <- .C("distance_geodesic_AB", as.double(locs1[,
      1] * pi/180), as.double(locs1[, 2] * pi/180), as.double(locs2[,
      1] * pi/180), as.double(locs2[, 2] * pi/180), as.double(d.out),
      as.integer(n1), as.integer(n2))[[5]]
  }
  else {
    D.Mx <- .C("distance_AB", as.double(locs1[, 1]), as.double(locs1[,
      2]), as.double(locs2[, 1]), as.double(locs2[, 2]),
      as.double(d.out), as.integer(n1), as.integer(n2))[[5]]
  }
  D.out <- matrix(D.Mx, n1, n2)
  return(D.out)
}

```

---

dlog.norm

*Local Search Function*

---

## Description

Local hyperparameter exponentiated-normal search function

**Usage**

```
dlog.norm(n, center, sd)
```

**Arguments**

n	Sample size. A positive scalar integer.
center	Exponential of the mean. A numeric scalar (or vector).
sd	Standard deviation. A numeric scalar (or vector).

**Details**

This function can be used by [MSS.snow](#).

**Value**

A numeric vector of length *n*.

**See Also**

[unif.mh](#), [MSS.snow](#), [fun.load](#).

**Examples**

```
x <- dlog.norm(100, 1, 1)
hist(x)

## The function is currently defined as
function (n, center, sd)
{
  return(exp(rnorm(n, log(center), sd)))
}
```

---

fun.load

*Stochastic Search Helper Functions*

---

**Description**

Functions that assign values and functions needed by [MSS.snow](#)

**Usage**

```
fun.load.hals.a()
fun.load.hals.fill()
fun.load.widals.a()
fun.load.widals.fill()
```

**Details**

Please see [MSS.snow](#) and examples.

**Value**

Nothing. The central role of these functions is the creation of four functions required by [MSS.snow](#): FUN.MH, FUN.GP, FUN.I, and FUN.EXIT. These four functions are assigned to the Global Environment. This [fun.load](#) suite of functions also passes needed objects (out-of-scope) to [snowfall](#) threads if the global user-made variable `run.parallel` is set to TRUE.

**See Also**

[MSS.snow](#)

**Examples**

```
### Here's an itty bitty example:
### we use stochastic search to find the minimum number in a vector
### GP isn't used here, and hence neither are p.ndx.ls nor f.d
### however, we still need to create them since MSS.snow requires their existence

fun.load.simpleExample <- function() {

  if( run.parallel ) {
    sfExport("xx")
  }

  p.ndx.ls <- list( c(1) )
  assign( "p.ndx.ls", p.ndx.ls, pos=globalenv() )
  f.d <- list( dlog.norm )
  assign( "f.d", f.d, pos=globalenv() )

  FUN.MH <- function(jj, GP.mx, X) {
    our.cost <- sample(xx, 1)
  }
  assign( "FUN.MH", FUN.MH, pos=globalenv() )

  FUN.GP <- NULL
  assign( "FUN.GP", FUN.GP, pos=globalenv() )

  FUN.I <- function(envmh, X) {
    cat( "Hello, I have found an even smaller number in xx ---> ", envmh$current.best, "\n" )
  }
  assign( "FUN.I", FUN.I, pos=globalenv() )

  FUN.EXIT <- function(envmh, X) {
    cat( "Done", "\n" )
  }
  assign( "FUN.EXIT", FUN.EXIT, pos=globalenv() )
}
```

```

xx <- 1:600

GP <- c(1)
MH.source <- fun.load.simpleExample

run.parallel <- TRUE
sfInit(TRUE, 2)
MSS.snow(MH.source, Inf, p.ndx.ls, f.d, matrix(1, nrow=28), 28, 7)
sfStop()

### Here's another itty bitty example:
### we use stochastic search to find the mean of a vector
### i.e., the argmin? of sum ( x - ? )^2

fun.load.simpleExample2 <- function() {

  if( run.parallel ) {
    sfExport("xx")
  }

  p.ndx.ls <- list( c(1) )
  assign( "p.ndx.ls", p.ndx.ls, pos=globalenv() )
  f.d <- list( unif.mh )
  assign( "f.d", f.d, pos=globalenv() )

  FUN.MH <- function(jj, GP.mx, X) {
    our.cost <- sum( ( xx - GP.mx[jj, 1] )^2 )
    return(our.cost)
  }
  assign( "FUN.MH", FUN.MH, pos=globalenv() )

  FUN.GP <- NULL
  assign( "FUN.GP", FUN.GP, pos=globalenv() )

  FUN.I <- function(envmh, X) {
    cat( "Improvement ---> ", envmh$current.best, " ---- ", envmh$GP, "\n" )
  }
  assign( "FUN.I", FUN.I, pos=globalenv() )

  FUN.EXIT <- function(envmh, X) {
    our.cost <- envmh$current.best
    GP <- envmh$GP
    cat( "Done", "\n" )
    cat( envmh$GP, our.cost, "\n" )
  }
  assign( "FUN.EXIT", FUN.EXIT, pos=globalenv() )
}

##set.seed(99999)

```

```
xx <- rnorm(300, 5, 10)

GP <- c(10)
MH.source <- fun.load.simpleExample2

run.parallel <- TRUE
sfInit(TRUE, 2)
MSS.snow(MH.source, Inf, p.ndx.ls, f.d, matrix(1/10, nrow=140, ncol=length(GP)), 140, 14)
sfStop()

##### in fact:
mean(xx)
```

---

fuse.Hst.ls

*Merge Contemporaneous Space-Time Covariates*

---

## Description

Fuse together two lists of spacio-temporal covariates

## Usage

```
fuse.Hst.ls(Hst.ls1, Hst.ls2)
```

## Arguments

Hst.ls1	Space-time covariates. A list of length $\tau$ , each element should be a numeric $n \times p_1$ matrix.
Hst.ls2	Space-time covariates. A list of length $\tau$ , each element should be a numeric $n \times p_2$ matrix.

## Value

An unnamed list of length  $\tau$ , each element will be a numeric  $n \times (p_1 + p_2)$  matrix.

## Examples

```
set.seed(9999)

tau <- 5
n <- 7

p1 <- 2
Hst.ls1 <- list()
for(i in 1:tau) { Hst.ls1[[i]] <- matrix(rnorm(n*p1), nrow=n) }

p2 <- 3
```

```

Hst.ls2 <- list()
for(i in 1:tau) { Hst.ls2[[i]] <- matrix(rnorm(n*p2), nrow=n) }

fuse.Hst.ls(Hst.ls1, Hst.ls2)

## The function is currently defined as
function (Hst.ls1, Hst.ls2)
{
  tau <- length(Hst.ls1)
  for (i in 1:tau) {
    Hst.ls1[[i]] <- cbind(Hst.ls1[[i]], Hst.ls2[[i]])
  }
  return(Hst.ls1)
}

```

---

H.als.b

*Adaptive Least Squares*

---

### Description

Adaptive Least Squares especially for large spacio-temporal data

### Usage

H.als.b(Z, Hs, Ht, Hst.ls, rho, reg, b.lag = -1, Hs0 = NULL, Ht0 = NULL, Hst0.ls = NULL)

### Arguments

Z	Space-time data. A $\tau \times n$ numeric matrix.
Hs	Spacial covariates (of supporting sites). An $n \times p_s$ numeric matrix.
Ht	Temporal covariates (of supporting sites). A $\tau \times p_t$ numeric matrix.
Hst.ls	Space-time covariates (of supporting sites). A list of length $\tau$ , each element should be a $n \times p_{st}$ numeric matrix.
rho	ALS signal-to-noise ratio (SNR). A non-negative scalar.
reg	ALS regularizer. A non-negative scalar.
b.lag	ALS lag. A scalar integer, typically -1 ( <i>a-prior</i> ), or 0 ( <i>a-posteriori</i> ).
Hs0	Spacial covariates (of interpolation sites). An $n^* \times p_s$ matrix, or NULL.
Ht0	Temporal covariates (of interpolation sites). A $\tau \times p_t$ matrix, or NULL. If not NULL, I cannot imagine a scenario where this shouldn't be Ht.
Hst0.ls	Space-time covariates (of interpolation sites). A list of length $\tau$ , each element should be a numeric $n \times p_{st}$ matrix.

**Value**

A named list.

Z.hat	A $\tau \times n$ matrix, the $i$ th row of which is the ALS prediction of the supporting sites at time $i$ .
B	A $\tau \times (p_s + p_t + p_{st})$ matrix, the $i$ th row of which is the ALS state (partial slopes) prediction at time $i$ .
Z0.hat	A $\tau \times n^*$ matrix, the $i$ th row of which is the ALS prediction of the interpolation sites at time $i$ .
inv.LHH	A $(p_s + p_t + p_{st}) \times (p_s + p_t + p_{st})$ matrix. This is the (ALS predicted) covariate precision matrix at time $\tau$ .
ALS.g	The ALS gain at time $\tau$ .

**Examples**

```

---

H.Earth.solar

*Solar Radiation*

---

### Description

Calculate Incident Solar Area (ISA)

### Usage

```
H.Earth.solar(x, y, dateDate)
```

### Arguments

x	Longitude. Numeric vector of length $n$ .
y	Latitude. Numeric vector of length $n$ .
dateDate	Posix date. Numeric vector of length $\tau$ .

### Details

This function returns a spacio-temporal covariate list (Earth's ISA is space-time *non-seperable*). A negative value indicates that at that time (list index), and at that location (matrix row), the sun is below the horizon all day.

### Value

An unnamed list of length  $\tau$ , each element of which is an  $n \times 1$  matrix.

### Examples

```

lat <- c(0, -88)
lon <- c(0, 0)
dateDate <- strptime( c('20120621', '20120320'), '%Y%m%d')

H.Earth.solar(lon, lat, dateDate)

## The function is currently defined as
function (x, y, dateDate)
{
  Hst.ls <- list()
  n <- length(y)

```

```

tau <- length(dateDate)
equinox <- strptime("20110320", "%Y%m%d")
for (i in 1:tau) {
  this.date <- dateDate[i]
  dfe <- as.integer(difftime(this.date, equinox, units = "day"))
  dfe
  psi <- 23.5 * sin(2 * pi * dfe/365.25)
  psi
  eta <- 90 - (360/(2 * pi)) * acos(cos(2 * pi * y/360) *
    cos(2 * pi * psi/360) + sin(2 * pi * y/360) * sin(2 *
    pi * psi/360))
  surface.area <- sin(2 * pi * eta/360)
  surface.area
  Hst.ls[[i]] <- cbind(surface.area)
}
return(Hst.ls)
}

```

---

Hals.fastcv.snow

*ALS Spacial Cross-Validation*

---

### Description

Fit Adaptive Least Squares with  $k$ -fold cross-validation

### Usage

```
Hals.fastcv.snow(j, rm.ndx, Z, Hs, Ht, Hst.ls, GP.mx)
```

### Arguments

<code>j</code>	Index used by <a href="#">snowfall</a> . A scalar integer. Which row of <code>GP.mx</code> to use for the ALS hyperparameters, GP.
<code>rm.ndx</code>	A list of vectors of indices to remove for $k$ -fold cross-validation.
<code>Z</code>	Data. A $\tau \times n$ numeric matrix.
<code>Hs</code>	Spacial covariates. An $n \times p_s$ numeric matrix.
<code>Ht</code>	Temporal covariates. An $\tau \times p_t$ numeric matrix.
<code>Hst.ls</code>	Space-time covariates. A list of length $\tau$ , each element containing a $n \times p_{st}$ numeric matrix.
<code>GP.mx</code>	Hyperparameters. A $k.glob \times 2$ non-negative matrix. See <a href="#">MSS.snow</a> .

### Value

A  $\tau \times n$  numeric matrix. The ALS cross-validated predictions of `Z`.

### See Also

Hals.ses

*Effective Standard Errors*

---

### Description

Calculate the ALS so-called 'effective standard errors'

### Usage

```
Hals.ses(Z, Hs, Ht, Hst.ls, rho, reg, b.lag, test.rng)
```

**Arguments**

Z	Space-time data. A $\tau \times n$ numeric matrix.
Hs	Spacial covariates (of supporting sites). An $n \times p_s$ numeric matrix.
Ht	Temporal covariates (of supporting sites). A $\tau \times p_t$ numeric matrix.
Hst.ls	Space-time covariates (of supporting sites). A list of length $\tau$ , each element should be a numeric $n \times p_{st}$ matrix.
rho	ALS signal-to-noise ratio (SNR). A non-negative scalar.
reg	ALS regularizer. A non-negative scalar.
b.lag	ALS lag. A scalar integer, typically -1 ( <i>a-prior</i> ), or 0 ( <i>a-posteriori</i> ).
test.rng	Temporal test range. A vector of temporal indices of the model test range.

**Value**

	A named list.
estimates	A $p_s + p_t + p_{st} \times 2$ matrix, each row giving the ALS partial slope estimate/prediction at time $\tau$ , and the 'effective standard error (prediction error)' for the partial slope.
inv.LHH	A $(p_s + p_t + p_{st}) \times (p_s + p_t + p_{st})$ matrix. This is the (ALS predicted) covariate precision matrix at time $\tau$ .
ALS.g	The ALS gain at time $\tau$ .

**Examples**

```
## Please see the example in H.als.b

```

---

Hst.sumup

---

*Create Covariance Matrix*

---

### Description

Calculate the covariance matrix of all model covariates

**Usage**

```
Hst.sumup(Hst.ls, Hs = NULL, Ht = NULL)
```

**Arguments**

Hst.ls	Space-time covariates. A list of length $\tau$ , each element containing a $n \times p_{st}$ numeric matrix.
Hs	Spacial covariates. An $n \times p_s$ numeric matrix.
Ht	Temporal covariates. An $\tau \times p_t$ numeric matrix.

**Details**

Important: The order of the arguments in this function is NOT the same as in the returned covariance matrix. The order in the covariance matrix is the same as in other functions in this package: Hs, Ht, Hst.ls.

**Value**

A  $(p_s + p_t + p_{st}) \times (p_s + p_t + p_{st})$  numeric, symmetric, non-negative definite matrix.

**Examples**

```
tau <- 20
n <- 10
Ht <- cbind(sin(1:tau), cos(1:tau))

Hs <- cbind(rnorm(10), rnorm(n, 5, 49))

Hst.ls <- list()
for(tt in 1:tau) {
  Hst.ls[[tt]] <- cbind(rnorm(n, 1, 0.1), rnorm(n, -200, 21))
}

Hst.sumup(Hst.ls, Hs, Ht)

##### standardize all covariates

x1 <- stnd.Hst.ls(Hst.ls, NULL)$sHst.ls
x2 <- stnd.Hs(Hs, NULL, FALSE)$sHs
x3 <- stnd.Ht(Ht, n)

Hst.sumup(x1, x2, x3)

## The function is currently defined as
```

```

function (Hst.ls, Hs = NULL, Ht = NULL)
{
  tau <- length(Hst.ls)
  if(tau < 1) { tau <- nrow(Ht) }
  if(is.null(tau)) { tau <- 10 ; cat("tau assumed to be 10.", "\n") }
  n <- nrow(Hst.ls[[1]])
  if(is.null(n)) { n <- nrow(Hs) }
  big.sum <- 0
  for (i in 1:tau) {

    }
    else {
      Ht.mx <- NULL
    }
    big.sum <- big.sum + crossprod(cbind(Hs, Ht.mx, Hst.ls[[i]]))
  }
  return(big.sum)
}

```

---

load.Hst.ls.2Zs

*Load Observations into Space-Time Covariates*

---

### Description

Insert an observation matrix into space-time covariates, but segregate based on missing values

### Usage

```
load.Hst.ls.2Zs(Z, Z.na, Hst.ls.Z, xwhich, rgr.lags = c(0))
```

### Arguments

Z	Observation data. A $\tau \times n$ numeric matrix.
Z.na	Missing data indicator. A $\tau \times n$ boolean matrix.
Hst.ls.Z	Space-time covariates. A list of length $\tau$ , each element should be a numeric $n \times p_{st}$ matrix.
xwhich	Which column-pair of Hst.ls.Z[[i]] to insert into the $i$ th row of Z. A scalar positive integer. By 'column-pair', we mean, e.g., a value of 1 will fill columns 1 and 2, a value of 2 will fill columns 3 and 4, a value of 3 will fill columns 5 and 6, etc.
rgr.lags	Temporal lagging of Z. A scalar integer.

## Details

This function, along with `load.Hst.ls.Z`, allows the user to convert a set of observations into covariates for another set of observations. Unlike `load.Hst.ls.Z`, this function *splits* `Z` based on the argument `Z.na`. Values associated with FALSE elements of `Z.na` are placed into the first column of the specified column-pair of `Hst.ls.Z`. Values associated with TRUE elements of `Z.na` are placed into the second column of the specified column-pair of `Hst.ls.Z` (all other values in the specified column-pair of `Hst.ls.Z` are zeroed).

## Value

An unnamed list of length  $\tau$ , each element will be a numeric  $n \times p_{st}$  matrix.

## See Also

[load.Hst.ls.Z](#).

## Examples

```
##### here's an itty-bitty example

```

**Arguments**

<code>FUN.source</code>	Search function definitions (see Details). A path to source code, or function, e.g., <a href="#">fun.load.widals.a</a> .
<code>current.best</code>	An initial cost. A scalar. Setting to NA will cause MSS.snow to make an initial pass over the data to create an initial cost to beat.
<code>p.ndx.ls</code>	Hyperparameter indices (of GP) to search. A list of vectors. For example, <code>list( c(1,2), c(3,4,5) )</code> will instruct MSS.snow, for each local search, to search over the first two hyperparameters as a pair, then to search the last three as a group.
<code>f.d</code>	Local search functions. A list of functions (one for each element of GP). Typically, for WIDALS, all five will be <a href="#">dlog.norm</a> .
<code>sds.mx</code>	The standard deviations for <code>f.d</code> . An $k.glob \times q$ matrix, where $q$ is the number of hyperparameters, i.e., the length of GP.
<code>k.glob</code>	The number of global searches. A scalar integer.
<code>k.loc.coef</code>	The coefficient for the number of local searches to make. A scalar integer.
<code>X</code>	A placeholder for values to be passed between functions inside MSS.snow (see Details).

**Details**

This function requires the presence of a number of values and functions out-of-scope. It is assumed that these are available in the Global Environment. They are: `run.parallel` (boolean), `FUN.MH` (a function that creates, for a given GP, a cost), `FUN.GP` (a function that applies constraints to GP), `FUN.I` (a function that does something when local searches have reduced the cost), `FUN.EXIT` (a function that does something when MSS.snow is done).

Examine the code for [fun.load.widals.a](#) for an example of the four functions described above. Note that these four functions may themselves require objects out-of-scope.

In general, for a given R session, special care should be taken concerning the naming and assigning of the following objects: `Z` (the space-time data), `Z.na` (a boolean matrix indicating missing values in `Z`), `locs` (site locations), `Hs` (spacial covariates), `Ht` (temporal covariates), `Hst.ls` (space-time covariates), `lags` (temporal lag vector), `b.lag` (the ALS lag), `cv` (cross-validation switch), `xgeodesic` (boolean), `ltco` (weight cut-off), `GP` (hyperparameter vector), `run.parallel` (boolean), `std.d` (boolean), `train.rng` (time index vector), `test.rng` (time index vector).

**Value**

Nothing. After completion, the best hyperparameters, GP, are assigned to the Global Environment.

03

*California Ozone***Description**

Daily airborne Ozone concentrations (ppb) over California, 68 fixed sensors, 2005-2006

**Usage**

```
data(03)
```

**Format**

The format is:

List of 5

\$Z : 'data.frame': 730 obs. of 68 variables: Ozone ppb for 68 sensors.

\$locs : 'data.frame': 68 obs. of 2 variables: longitude, latitude for 68 sites.

\$helevs : elevations (meters) for 68 sites.

\$locs0 : 2358 obs. of 2 variables: longitude, latitude for interpolation grid.

\$helevs0: elevations (meters) for 2358 interpolation grid sites.

**Source**

The Ozone data originates from the California Air Resources Board (CARB). The interpolation grid elevations originate from the Google Elevation API.

**References**

The O3 data comes from the DVD-ROM offered gratis by CARB: <http://www.arb.ca.gov/aqd/aqcd/aqcd.htm>

**Examples**

```
data(O3)
```

---

```
rm.cols.Hst.ls          Remove Space-Time Covariates from Model
```

---

**Description**

Remove spacial covariates from space-time covariate list

**Usage**

```
rm.cols.Hst.ls(Hst.ls, rm.col.ndx)
```

**Arguments**

**Hst.ls**               Space-time covariates (of supporting sites). A list of length  $\tau$ , each element should be a numeric  $n \times p_{st}$  matrix.

**rm.col.ndx**          Which columns of Hst.ls to remove. A positive scalar integer.

**Value**

An unnamed list of length  $\tau$ , each element will be a numeric  $n \times p_{st} - p_r m$  matrix, where  $p_r m$  is the length of rm.col.ndx.

**Examples**

```
tau <- 21
n <- 7

pst <- 5
Hst.ls <- list()
for(i in 1:tau) { Hst.ls[[i]] <- matrix(1:pst, n, pst, byrow=TRUE) }

rm.cols.Hst.ls(Hst.ls, c(1,3))

stnd.Hs

*Standardize Spatial Covariates*

---

### Description

Standardize spatial covariates with respect to both the space and time dimensions

### Usage

```
stnd.Hs(Hs, Hs0 = NULL, intercept = TRUE)
```

### Arguments

Hs	Spacial covariates (of supporting sites). An $n \times p_s$ numeric matrix.
Hs0	Spacial covariates (of interpolation sites). An $n^* \times p_s$ numeric matrix.
intercept	Include intercept term? Boolean.

### Value

A named list.

sHs	An $n \times p_s$ numeric matrix.
sHs0	An $n^* \times p_s$ numeric matrix.
h.mean	The covariates' mean over space.
h.sd	The covariates' standard deviation over space.
n	Number of support sites.
intercept	The supplied intercept argument.

stnd.Hst.ls

Standardize Space-Time Covariates

---

### Description

Standardize spacio-temporal covariates with respect to both the spacial and time dimensions

### Usage

```
stnd.Hst.ls(Hst.ls, Hst0.ls = NULL)
```

### Arguments

Hst.ls	Space-time covariates (of supporting sites). A list of length $\tau$ , each element should be a numeric $n \times p_{st}$ matrix.
Hst0.ls	Space-time covariates (of interpolation sites). A list of length $\tau$ , each element should be a numeric $n^* \times p_{st}$ matrix.

### Value

A named list.

sHst.ls	A list of length $\tau$ , each element a numeric $n \times p_{st}$ matrix.
sHst0.ls	A list of length $\tau$ , each element a $n^* \times p_{st}$ matrix
h.mean	The covariates' mean over space-time.
h.sd	The covariates' standard deviation over space-time.

---

stnd.Ht

*Standardize Temporal Covariates*

---

**Description**

Standardize temporal covariates with respect to both the spacial and time dimensions

**Usage**

stnd.Ht(Ht, n)

**Arguments**

Ht                    Temporal covariates (of supporting sites). A  $\tau \times p_t$  numeric matrix.  
n                      Number of sites. A positive scalar integer.

**Value**

A  $\tau \times p_t$  numeric matrix.

**See Also**

[stnd.Hs](#), [stnd.Hst.ls](#).

```

---

subsetsites.Hst.ls      *Site-Wise Extract Space-Time Covariates*

---

**Description**

Extract space-time covariates by site

**Usage**

```
subsetsites.Hst.ls(Hst.ls, xmask)
```

**Arguments**

Hst.ls                Space-time covariates. A list of length  $\tau$ , each element should be a  $n \times p_{st}$  numeric matrix.  
xmask                 Which sites to remove from Hst.ls. A boolean vector of length  $n$ , or a vector of spacial indices.

**Value**

Space-time covariates. A list of length  $\tau$ , each element a  $c \times p_s t$  numeric matrix, where  $c$  is the number of TRUE's in boolean `xmask`, or length of index `xmask`.

**Examples**

```
tau <- 70
n <- 28

Hst.ls <- list()
for(i in 1:tau) { Hst.ls[[i]] <- matrix(rnorm(n*4), nrow=n) }

subsetsites.Hst.ls(Hst.ls, c(1,3,10))

  }
  return(Hst.ls.out)
}
```

---

unif.mh

*Local Search Function*

---

**Description**

Search function

**Usage**

```
unif.mh(n, center, sd)
```

**Arguments**

<code>n</code>	Sample size. A positive scalar integer.
<code>center</code>	Mean. A numeric scalar (or vector).
<code>sd</code>	Standard deviation. A numeric scalar (or vector).

**Value**

A numeric vector of length  $n$ .

**See Also**

[dlog.norm](#), [MSS.snow](#).

**Examples**

```
x <- unif.mh(100, 1, 1)
hist(x)

## The function is currently defined as
function (n, center, sd)

  w <- sd * sqrt(3)
  a <- center - w
  b <- center + w
  x <- runif(n, a, b)
  return(x)
}
```

---

 unload.Hst.ls

---

*Convert a Space-Time Covariate into Data*

---

**Description**

Convert a spacio-temporal covariate into contemporaneous data

**Usage**

```
unload.Hst.ls(Hst.ls, which.col, rgr.lags)
```

**Arguments**

Hst.ls	Space-time covariates. A list of length $\tau$ , each element should be a $n \times p_{st}$ numeric matrix.
which.col	Which column of Hst.ls[[i]] to insert into the $i$ th row of Z. A scalar positive integer.
rgr.lags	Temporal lagging of Z. A scalar integer.

**Value**

A numeric  $\tau \times n$  matrix.

**See Also**

[load.Hst.ls.Z](#), [load.Hst.ls.2Zs](#).

**Examples**

```
##### here's an itty-bitty example

tau <- 7
n <- 5

Hst.ls <- list()
for(i in 1:tau) { Hst.ls[[i]] <- matrix(rnorm(n*4), nrow=n) }

Zh <- unload.Hst.ls(Hst.ls, 1, 0)

## The function is currently defined as
function (Hst.ls, which.col, rgr.lags)
{
  n <- nrow(Hst.ls[[1]])
  tau <- length(Hst.ls)
  Z.out <- matrix(NA, tau, n)
  min.ndx <- max(1, -min(rgr.lags) + 1)
  max.ndx <- min(tau, tau - max(rgr.lags))
  for (i in min.ndx:max.ndx) {
    Z.out[i - rgr.lags, ] <- Hst.ls[[i]][, which.col]
  }
  return(Z.out)
}
```

---

widals.predict

*WIDALS Interpolation*

---

**Description**

Interpolate to unmonitored sites using WIDALS

**Usage**

```
widals.predict(Z, Hs, Ht, Hst.ls, locs, lags, b.lag, Hs0, Hst0.ls, locs0,
geodesic = FALSE, wrap.around = NULL, GP, std.d = FALSE, ltco = -16)
```

**Arguments**

Z	Space-time data. A $\tau \times n$ numeric matrix.
Hs	Spacial covariates (of supporting sites). An $n \times p_s$ numeric matrix.
Ht	Temporal covariates (of supporting sites). A $\tau \times p_t$ numeric matrix.
Hst.ls	Space-time covariates (of supporting sites). A list of length $\tau$ , each element should be a $n \times p_{st}$ numeric matrix.

locs	Locations of supporting sites. An $n \times 2$ numeric matrix, first column is spacial $x$ , second column is spacial $y$ . If the geodesic is TRUE, make sure latitude is in the first column.
lags	Temporal lags for stochastic smoothing. An integer vector or scalar. E.g., if the data's time increment is daily, then <code>lags = c(-1, 0, 1)</code> would tell the enclosed function <code>crispify</code> smooth today's predictions using yesterdays, today's, and tomorrow's observed residuals.
b.lag	ALS lag. A scalar integer, typically -1 ( <i>a-prior</i> ), or 0 ( <i>a-posteriori</i> ).
Hs0	Spacial covariates (of interpolation sites). An $n^* \times p_s$ matrix, or NULL.
Hst0.ls	Space-time covariates (of interpolation sites). A list of length $\tau$ , each element should be a numeric $n \times p_{st}$ matrix.
locs0	Locations of interpolation sites. An $n^* \times 2$ numeric matrix. See locs argument above.
geodesic	Use geodesic distance? Boolean. If true, distance (used internally) is in units kilometers.
wrap.around	**Unused.
GP	Widals hyperparameters. A non-negative vector.
stnd.d	Spacial compression. Boolean.
ltco	Weight threshold. A scalar number. A value of, e.g., -10, will instruct <code>crispify</code> to ignore weights less than $10^{(-10)}$ when smoothing.

**Value**

A  $\tau \times n^*$  matrix. The WIDALS predictions at locs0.

**See Also**

`crispify`, `H.als.b`, `widals.snow`.

**Examples**

```
#### similar to example provided in H.als.b

```

---

widals.snow

*Fit WIDALS*

---

## Description

Locate the WIDALS hyperparameters

## Usage

```

widals.snow(j, rm.ndx, Z, Hs, Ht, Hst.ls, locs, lags, b.lag, cv = 0,
  geodesic = FALSE, wrap.around = NULL, GP.mx, stnd.d = FALSE, ltco = -16)

```

**Arguments**

j	Index used by <a href="#">snowfall</a> . A scalar integer. Which row of GP.mx to use for the ALS hyperparameters, GP.
rm.ndx	A list of vectors of indices to remove for $k$ -fold cross-validation.
Z	Data. A $\tau \times n$ numeric matrix.
Hs	Spacial covariates. An $n \times p_s$ numeric matrix.
Ht	Temporal covariates. A $\tau \times p_t$ numeric matrix.
Hst.lis	Space-time covariates. A list of length $\tau$ , each element containing a $n \times p_{st}$ numeric matrix.
locs	Locations of supporting sites. An $n \times 2$ numeric matrix, first column is spacial $x$ , second column is spacial $y$ . If the geodesic is TRUE, make sure latitude is in the first column.
lags	Temporal lags for stochastic smoothing. An integer vector or scalar. E.g., if the data's time increment is daily, then lags = c(-1, 0, 1) would tell the enclosed function <a href="#">crispify</a> smooth today's predictions using yesterdays, today's, and tomorrow's observed residuals.
b.lag	ALS lag. A scalar integer, typically -1 ( <i>a-prior</i> ), or 0 ( <i>a-posteriori</i> ).
cv	Cross-validation switch. Currently takes on a value of -2 or 2. See Details below.
geodesic	Use geodesic distance? Boolean. If true, distance (used internally) is in units kilometers.
wrap.around	**Unused.
GP.mx	Hyperparameters. A $k.glob \times 2$ non-negative matrix. See <a href="#">MSS.snow</a> .
stnd.d	Spacial compression. Boolean.
ltco	Weight threshold. A scalar number. A value of, e.g., -10, will instruct <a href="#">crispify</a> to ignore weights less than $10^{(-10)}$ when smoothing.

**Details**

When the cv is set to 2, then this function uses spacial  $k$ -fold validation, according to the site indices present in rm.ndx. When cv is set to -2, self-referencing sites are given zero-weight, i.e., a site's value is not allowed to contribute to its predicted value.

**Value**

A  $\tau \times n$  matrix. The WIDALS predictions at locs.

}

```

**Description**

A crude, brute-force way to destroy bad values in data.

**Usage**

```
Z.clean.up(Z)
```

**Arguments**

Z                    Data. A  $\tau \times n$  matrix.

**Details**

This function replaces intractable values, e.g., NA, or  $-\text{Inf}$ , in data, with the global mean.

**Value**

A  $\tau \times n$  numeric matrix.

**Examples**

```
tau <- 10
n <- 7

Z <- matrix(1, tau, n)
Z[2,4] <- -Inf
Z[3,4] <- Inf
Z[4,4] <- NA
Z[5,4] <- log(-1)
Z

Z.clean.up(Z)

## The function is currently defined as
function (Z)
{
  Z[Z == Inf | Z == -Inf] <- NA
  Z[is.na(Z) | is.nan(Z)] <- mean(Z, na.rm = TRUE)
  return(Z)
}
```
