Bayesian-Multiplicative replacement of count zeros

Description
This function implements methods for imputing zeros in compositional count data sets based on a Bayesian-multiplicative replacement.

Usage
```r
cmultRepl(X, label = 0,  
method = c("GBM","SQ","BL","CZM","user"), output = c("prop","p-counts"),  
delta = 0.65, threshold = 0.5, correct = TRUE, t = NULL, s = NULL,  
suppress.print = FALSE)
```

Arguments

- **X**
  Count data set (matrix or data.frame class).

- **label**
  Unique label (numeric or character) used to denote count zeros in X (default label=0).

- **method**
  Geometric Bayesian multiplicative (GBM, default); square root BM (SQ); Bayes-Laplace BM (BL); count zero multiplicative (CZM); user-specified hyper-parameters (user).

- **output**
  Output format: imputed proportions (prop, default) or pseudo-counts (p-counts).

- **delta**
  If method="CZM", fraction of the upper threshold used to impute zeros (default delta=0.65). Also, fraction of the lowest estimated probability used to correct imputed proportions falling above it (when correct=TRUE).

- **threshold**
  For a vector of counts, factor applied to the quotient 1 over the number of trials (sum of the counts) used to produce an upper limit for replacing zero counts by the CZM method (default threshold=0.5).

- **correct**
  Logical vector setting whether imputed proportions falling above the lowest estimated probability for a multinomial part must be corrected or not (default correct=TRUE).
**cmultRepl**

- **t**  If `method="user"`, user-specified $t$ hyper-parameter of the Dirichlet prior distribution for each count vector (row) in $X$. It must be a matrix of the same dimensions as $X$.

- **s**  If `method="user"`, user-specified $s$ hyper-parameter of the Dirichlet prior distribution for each count vector (row) in $X$. It must be a vector of length equal to the number of rows of $X$.

- **suppress.print**  Suppress printed feedback (default).

### Details

Zero counts, assumed to be due to under-reporting or limited sampling, are imputed under a Bayesian paradigm (GBM, SQ or BL method) by posterior estimates of the multinomial probabilities generating the counts, assuming a Dirichlet prior distribution. The argument `method` sets the Dirichlet hyper-parameters $t$ (prior estimates of multinomial probabilities) and $s$ (strength). The user can specify their own by setting `method="user"` and entering them as $t$ and $s$ arguments. Note that, under certain circumstances (see references for details), these methods can generate imputed proportions falling above the lowest estimated probability of a multinomial part ($c/n$, where $c$ is the count and $n$ is the number of trials). In such cases, the imputation is corrected by using a fraction ($\delta$) of the minimum $c/n$ for that part. Lastly, the non-zero parts are multiplicatively adjusted according to their compositional nature.

On the other hand, `method="CZM"` uses multiplicative simple replacement (`multRepl`) on the matrix of estimated probabilities. The upper limit and the fraction $\delta$ used are specified by, respectively, the arguments `threshold` and `delta`. Suggested values are `threshold=0.5` (so the upper limit for a multinomial probability turns out to be $0.5/n$), and `delta=0.65` (so the imputed proportion is 65% of the upper limit).

### Value

By default (output="prop") the function returns an imputed data set (data.frame class) in proportions (estimated probabilities). Alternatively, these proportions are re-scaled to produce a compositionally-equivalent matrix of pseudo-counts (output="p-counts") which preserves the ratios between parts. When `correct=TRUE` and `verbose=TRUE`, the number of times, if any, an imputed proportion was corrected to fall below the minimum estimated multinomial probability is printed.

**lcTest**

*Log-contrast homogeneity test*

**Description**

This function tests for homogeneity across groups of means and variances of user-defined log-contrasts. Groups can be defined by either zero/unobserved data patterns or by a grouping factor in fully observed zero-free data sets.

**Usage**

lcTest(X, label = 0, groups = NULL, lc = NULL, method = c("parametric", "nonparametric"), b = 1000)

**Arguments**

- **X**: Compositional data set (*matrix* or *data.frame* class).
- **label**: Unique label (*numeric* or *character*) used to denote zero or unobserved data in X (label = 0, default).
- **groups**: Grouping factor in fully observed zero-free data sets (groups = NULL, default).
- **lc**: User-defined log-contrast (see details below).
- **method**: Approach used for mean and variance homogeneity testing (method = "parametric", default).
- **b**: Number of bootstrap resamples used by permutation test (b = 1000, default).

**Details**

Homogeneity of log-contrast means and variances across groups is tested using either parametric or non-parametric tests. When method = "parametric", ordinary analysis of variance and Bartlett’s tests are used. Alternatively, Kruskal-Wallis and Fligner-Killen tests are used instead when method = "nonparametric". The results of a permutation test of homogeneity of variation arrays based on total weighted squared relative errors are also provided (see zVarArrayTest for more details). The log-contrast is specified by the lc argument using a vector of codes 1, -1 and 0 for components in the numerator, denominator and omitted respectively.

**Value**

Test p-values for log-contrast means and variances.

Description
This function implements a simulation-based Data Augmentation (DA) algorithm to impute left-censored values (e.g. values below detection limit, rounded zeros) via coordinates representation of compositional data sets which incorporate the information of the relative covariance structure. Alternatively, this function can be used to impute missing data. Multiple imputation estimates can also be obtained from the output.

Usage
lrDA(X, label = NULL, dl = NULL,
    ini.cov=c("lrEM","complete.obs","multRepl"), delta = 0.65,
    imp.missing = FALSE, n.iters = 1000, m = 1, store.mi = FALSE, closure = NULL)
Arguments

X Compositional data set (matrix or data.frame class).

label Unique label (numeric or character) used to denote unobserved left-censored values in X.

dl Numeric vector or matrix of detection limits/thresholds. These must be given on the same scale as X.

ini.cov Initial estimation of the log-ratio covariance matrix. It can be based on lrEM estimation ("lrEM", default), complete observations ("complete.obs") or multiplicative simple replacement ("multRepl").

delta If ini.cov="multRepl", delta parameter for initial multiplicative simple replacement (multRepl) in proportions (default = 0.65).

imp.missing If TRUE then unobserved data identified by label are treated as missing data (default = FALSE).

n.iters Number of iterations for the DA algorithm (default = 1000).

m Number of multiple imputations (default = 1).

store.mi Logical value. If m>1 creates a list with m imputed data matrices. (store.mi=FALSE, default).

closure Closure value used to add a residual part if needed when multiplicative simple replacement is used to initiate the DA algorithm, either directly (ini.cov="multRepl") or as part of lrEM estimation (ini.cov="lrEM") (see ?multRepl).

Details

After convergence of the Markov chain Monte Carlo (MCMC) iterative process to its steady state, this function imputes unobserved compositional parts by simulated values from their posterior predictive distributions through coordinates representation, given the information from the observed data. For left-censoring problems, it allows for either single (vector form) or multiple (matrix form, same size as X) limits of detection by component. Any threshold value can be set for non-censored elements (e.g. use 0 if no threshold for a particular column or element of the data matrix).

It produces imputed data sets on the same scale as the input data set. If X is not closed to a constant sum, then the results are adjusted to provide a compositionally equivalent data set, expressed in the original scale, which leaves the absolute values of the observed components unaltered.

The common conjugate normal inverted-Wishart distribution with non-informative Jeffreys prior has been assumed for the model parameters in the coordinates space. Under this setting, convergence is expected to be fast (n.iters set to 1000 by default). Besides, considering EM parameter estimates as initial point for the DA algorithm (ini.cov="lrEM") assures faster convergence by starting near the centre of the posterior distribution.

By setting m greater than 1, the procedure also allows for multiple imputations of the censored values drawn at regular intervals after convergence. In this case, in addition to the burn-in period for convergence, n.iters determines the gap, large enough to prevent from correlated values, between successive imputations. The total number of iterations is then n.iters*m. By default, a single imputed data set results from averaging the m imputations in the space of coordinates. If store.mi=TRUE, a list with m imputed data sets is generated instead.
In the case of censoring patterns involving samples containing only one observed component, these are imputed by multiplicative simple replacement (`multRepl`) and a warning message identifying them is printed.

**Missing data imputation**

This function can be employed to impute missing data by setting `imp.missing = TRUE`. For this case, the argument `label` indicates the unique label for missing values. The argument `dl` is ignored as it is meaningless here.

**Value**

A `data.frame` object containing the imputed compositional data set in the same scale as the original, or a `list` of imputed data sets if multiple imputation is carried out (`m>1`) and `store.mi=TRUE`.

lrEM

Log-ratio EM algorithm

Description

This function implements model-based ordinary and robust Expectation-Maximisation algorithms to impute left-censored data (e.g. values below detection limit, rounded zeros) via coordinates representation of compositional data which incorporate the information of the relative covariance structure. Alternatively, this function can be used to impute missing data.

Usage

```R
lrEM(X, label = NULL, dl = NULL, rob = FALSE,
    ini.cov = c("complete.obs", "multRepl"), delta = 0.65,
    tolerance = 0.0001, max.iter = 50, rlm.maxit = 150,
    imp.missing = FALSE, suppress.print = FALSE, closure = NULL)
```

Arguments

- **X**: Compositional data set (matrix or data.frame class).
- **label**: Unique label (numeric or character) used to denote unobserved values in X.
- **dl**: Numeric vector or matrix of detection limits/thresholds. These must be given on the same scale as X.
- **rob**: Logical value. FALSE provides maximum-likelihood estimates of model parameters (default), TRUE provides robust parameter estimates.
ini.cov

Initial estimation of either the log-ratio covariance matrix (ML estimation) or unobserved data (robust estimation). It can be based on either complete observations ("complete.obs", default) or multiplicative simple replacement ("multRepl").

delta

If ini.cov="multRepl", delta parameter for initial multiplicative simple replacement of left-censored data (see multRepl) expressed in proportions (default = 0.65).

tolerance

Convergence criterion for the EM algorithm (default = 0.0001).

max.iter

Maximum number of iterations for the EM algorithm (default = 50).

rlm.maxit

If rob=TRUE, maximum number of iterations for the embedded robust regression estimation (default = 150; see rlm in MASS package for details).

imp.missing

If TRUE then unobserved data identified by label are treated as missing data (default = FALSE).

suppress.print

Suppress printed feedback (suppress.print = FALSE, default).

closure

Closure value used to add a residual part if needed when ini.cov="multRepl" is used (see ?multRepl).

Details

After convergence, this function imputes unobserved compositional data by their estimated conditional expected values through coordinates representation, given the information from the observed data. For left-censoring problems, it allows for either single (vector form) or multiple (matrix form, same size as X) limits of detection by component. Any threshold value can be set for non-censored elements (e.g. use 0 if no threshold for a particular column or element of the data matrix).

It produces an imputed data set on the same scale as the input data set. If X is not closed to a constant sum, then the results are adjusted to provide a compositionally equivalent data set, expressed in the original scale, which leaves the absolute values of the observed components unaltered.

Under maximum likelihood (ML) estimation (default, rob=FALSE), a correction factor based on the residual covariance obtained by censored regression is applied for the correct estimation of the conditional covariance matrix in the maximisation step of the EM algorithm. This is required in order to obtain the conditional expectation of the sum of cross-products between two components in the case that both involve imputed values. Note that the procedure is based on the oblique additive log-ratio (alr) transformation to simplify calculations and alleviates computational burden. Nonetheless, the same results would be obtained using an isometric log-ratio transformation (ilr). Note also that alr requires at least one complete column. Otherwise, a preliminary imputation, e.g. by multRepl or multLN, of the most simplest censoring pattern may be enough. The argument ini.cov determines how the initial estimation of the log-ratio covariance matrix required to start the EM process is worked out.

Under robust estimation (rob=TRUE), the algorithm requires ilr transformations in order to satisfy requirements for robust estimation methods (MM-estimation by default, see rlm function for more details). An initial estimation of nondetects is required to get the algorithm started. This can be based on either the subset of fully observed cases (ini.cov="complete.obs") or a multiplicative simple replacement of all nondetects in the data set (ini.cov="multRepl"). Note that the robust regression method involved includes random elements which can, occasionally, give rise to NaN values getting the routine execution halted. If this happened, we suggest to simply re-run the function once again.
Note that conditional imputation based on log-ratio coordinates cannot be conducted when there exist censoring patterns including samples with only one observed component. As a workaround, lrEM applies multiplicative simple replacement (multRepl) on those and a warning message identifying the problematic cases is printed. Alternatively, it might be sensible to simply remove those non-informative samples from the data set.

**Missing data imputation**

This function can be employed to impute missing data with their conditional expectation using the EM algorithm under regular conditions by setting `imp.missing = TRUE`. Either maximum-likelihood or robust estimation can be used through the `rob` argument. For this case, the argument `label` indicates the unique label for missing values. The algorithm can be initiated using either "complete.obs" or "multRepl" (for missing data) as specified by the `ini.cov` argument. The argument `dl` is ignored as it is meaningless here.

**Value**

A data.frame object containing the imputed compositional data set in the same scale as the original. The number of iterations required for convergence is also printed (this can be suppressed by setting `suppress.print=TRUE`).

```r
# Data set closed to 100 (percentages, common dl = 1%)
X <- matrix(c(26.91,8.08,12.59,31.58,6.45,14.39,
              39.73,26.20,0.00,15.22,6.80,12.05,
              10.76,31.36,7.10,12.74,31.34,6.70,
              10.85,46.40,31.89,10.86,0.00,0.00,
              7.57,11.35,30.24,6.39,13.65,30.80,
              38.09,7.62,23.68,9.70,20.91,0.00,
              12.85,14.00,30.00,10.00,10.00,20.00),
             nrow=10, ncol=6)
X <- lrEM(X) # lrEM function
```

The function `lrEMplus` implements an extended version of the log-ratio EM algorithm (`lrEM` function) to simultaneously deal with both zeros (i.e. data below detection limit, rounded zeros) and missing data in compositional data sets.

**Description**

This function implements an extended version of the log-ratio EM algorithm (`lrEM` function) to simultaneously deal with both zeros (i.e. data below detection limit, rounded zeros) and missing data in compositional data sets.
Note: zeros and missing data must be labelled using 0 and NA respectively to use this function.

Usage

```r
lrEMplus(X, dl = NULL, rob = FALSE,
    ini.cov = c("complete.obs", "multRepl"), delta = 0.65,
    tolerance = 0.0001, max.iter = 50, rlm.maxit = 150,
    suppress.print = FALSE, closure = NULL)
```

Arguments

- **X**: Compositional data set (matrix or data.frame class).
- **dl**: Numeric vector or matrix of detection limits/thresholds. These must be given on the same scale as X.
- **rob**: Logical value. FALSE provides maximum-likelihood estimates of model parameters (default), TRUE provides robust parameter estimates.
- **ini.cov**: Initial estimation of either the log-ratio covariance matrix (ML estimation) or unobserved data (robust estimation). It can be based on either complete observations ("complete.obs", default) or multiplicative simple replacement ("multRepl").
- **delta**: If ini.cov="multRepl", delta parameter for initial multiplicative simple replacement of left-censored data (see multRepl) expressed in proportions (default = 0.65).
- **tolerance**: Convergence criterion (default = 0.0001).
- **max.iter**: Maximum number of iterations (default = 50).
- **rlm.maxit**: If rob=TRUE, maximum number of iterations for the embedded robust regression estimation (default = 150; see rlm in MASS package for details).
- **suppress.print**: Suppress printed feedback (suppress.print = FALSE, default).
- **closure**: Closure value used to add a residual part if needed when ini.cov="multRepl" is used (see ?multRepl).

Details

The procedure starts with an initial imputation of either zeros (using simple replacement with delta*dl) or missing values (using geometric mean imputation from observed data) depending of which problem is the least frequent in the data set. Subsequently, iterative calls to lrEM replace zeros and missing data alternately until convergence to a stable solution or the maximum number of iterations is reached.

See ?lrEM for more details.

Value

A data.frame object containing the imputed compositional data set in the same scale as the original. The number of iterations required for convergence is also printed (this can be suppressed by setting suppress.print=TRUE).

**multKM**

*Multiplicative Kaplan-Meier smoothing spline (KMSS) replacement*

**Description**

This function implements non-parametric multiplicative KMSS imputation of left-censored values (e.g. values below detection limit, rounded zeros) in compositional data sets. It is based on simulation from a smoothing spline fitted to the Kaplan-Meier (KM) estimate of the empirical cumulative distribution function (ECDF) of the data.

**Usage**

multKM(X, label = NULL, dl = NULL, n.draws = 1000, n.knots = NULL)
Arguments

- **X**: Compositional data set (matrix or data.frame class).
- **label**: Unique label (numeric or character) used to denote unobserved left-censored values in X.
- **dl**: Numeric vector or matrix of detection limits/thresholds. These must be given on the same scale as X.
- **n.draws**: Number of random draws from the inverse KM ECDF generated to produce an averaged imputed value (n.draws=1000, default).
- **n.knots**: Integer or function giving the number of knots used for fitting a cubic smoothing spline to the KM ECDF (see smooth.spline for default value). It allows for a vector or list of settings per column of X.

Details

This function imputes left-censored compositional values by averaging (geometric mean) n random draws (n.draws argument) from a cubic smoothing spline curve fitting the inverse KM ECDF below the corresponding limit of detection or censoring threshold. It then applies a multiplicative adjustment to preserve the multivariate compositional properties of the samples. It allows for either single (vector form) or multiple (matrix form, same size as X) limits of detection by component. Although note that it is equivalent to simple substitution by the limit of detection for singly censored components. Any threshold value can be set for non-censored elements (e.g. use 0 if no threshold for a particular column or element of the data matrix).

It produces an imputed data set on the same scale as the input data set. If X is not closed to a constant sum, then the results are adjusted to provide a compositionally equivalent data set, expressed in the original scale, which leaves the absolute values of the observed components unaltered.

The level of smoothing of the estimated spline can be controlled by the n.knots argument. The function splineKM can assist in choosing a finer value, although the default setting works generally well.

Value

A data.frame object containing the imputed compositional data set in the same scale as the original.

---

**multLN**

*Multiplicative lognormal replacement*

**Description**

This function implements model-based multiplicative lognormal imputation of left-censored values (e.g. values below detection limit, rounded zeros) in compositional data sets.

**Usage**

`multLN(X, label = NULL, dl = NULL, rob = FALSE, random = FALSE)`

**Arguments**

- **X**
  - Compositional data set (`matrix` or `data.frame` class).
- **label**
  - Unique label (`numeric` or `character`) used to denote unobserved left-censored values in `X`.
- **dl**
  - Numeric vector or matrix of detection limits/thresholds. These must be given on the same scale as `X`.
- **rob**
  - Logical value. `FALSE` provides maximum-likelihood estimates of model parameters (default), `TRUE` provides robust estimates (see NADA package for details).
- **random**
  - Logical value. Values imputed using either estimated geometric mean (`FALSE`, default) or random values (`TRUE`) below the limit of detection.

**Details**

By default, this function imputes left-censored compositional values by the estimated geometric mean of the values below the corresponding limit of detection or censoring threshold and applies a multiplicative adjustment to preserve the multivariate compositional properties of the samples. Alternatively, imputation can be carried out by random values below the limit of detection (`random = TRUE`) based on a normal distribution on the positive real line (see below).
It depends on package NADA to produce the required model parameter estimates (either maximum likelihood or robust regression on order statistics). It allows for either single (vector form) or multiple (matrix form, same size as X) limits of detection by component. Any threshold value can be set for non-censored elements (e.g. use 0 if no threshold for a particular column or element of the data matrix).

It produces an imputed data set on the same scale as the input data set. If X is not closed to a constant sum, then the results are adjusted to provide a compositionally equivalent data set, expressed in the original scale, which leaves the absolute values of the observed components unaltered. Note that a normal distribution on the positive real line is considered. That is, it is defined with respect to a measure according to own geometry of the positive real line, instead of the standard lognormal based on the Lebesgue measure in real space.

Value

A data.frame object containing the imputed compositional data set in the same scale as the original.

X_multLN <- multLN(X,label=0,dl=rep(1,6))

# Multiple limits of detection by component
mdl <- matrix(0,ncol=6,nrow=10)
multRepl

Description

This function implements non-parametric multiplicative simple imputation of left-censored (e.g. values below detection limit, rounded zeros) and missing data in compositional data sets.

Usage

```
multRepl(X, label = NULL, dl = NULL, delta = 0.65, imp.missing = FALSE, closure = NULL)
```
Arguments

X Compositional vector (numeric class) or data set (matrix or data.frame class).

label Unique label (numeric or character) used to denote unobserved values in X.

dl Numeric vector or matrix of detection limits/thresholds. These must be given on the same scale as X.

delta Delta parameter (fraction of the threshold) used in proportions (default = 0.65).

imp.missing If TRUE then unobserved values identified by label are treated as missing data (default = FALSE).

closure Closure value used to add a residual part for imputation (see below).

Details

This function imputes left-censored compositional values by a given fraction delta of the corresponding limit of detection and applies a multiplicative adjustment to preserve the multivariate compositional properties of the samples. It allows for either single (vector form) or multiple (matrix form, same size as X) limits of detection by component. Any threshold value can be set for non-censored elements (e.g. use 0 if no threshold for a particular column or element of the data matrix).

**Missing data imputation:** missing data can be imputed by setting imp.missing = TRUE. They are replaced by the estimated column geometric mean from observed values. The non-missing parts in the composition are applied multiplicative adjustment. The argument dl and delta are ignored and X is require to be a data matrix in this case.

Note: negative values can be generated when unobserved components are a large portion of the composition, which is more likely for missing data (e.g in major chemical elements) and non-closed compositions. A workaround is to add a residual filling the gap up to the closure/total when possible. This is done internally when a value for closure is specified (e.g. closure=10^6 if ppm or closure=100 if percentages). The residual is discarded after imputation.

This function produces an imputed data set on the same scale as the input data set. If X is not closed to a constant sum, then the results are adjusted to provide a compositionally equivalent data set, expressed in the original scale, which leaves the absolute values of the observed components unaltered. Note that this adjustment only applies to data sets and not when a single composition is entered. In this latter case, the composition is treated as a closed vector.

Value

A data.frame object containing the imputed compositional vector or data set in the same scale as the original.

multReplus

Multiplicative simple replacement (plus)

Description

This function implements an extended version of multiplicative simple imputation (multRep1 function) to simultaneously deal with both zeros (i.e. data below detection limit, rounded zeros) and missing data in compositional data sets.

Note: zeros and missing data must be labelled using 0 and NA respectively to use this function.

Usage

multReplus(X, dl = NULL, delta = 0.65, suppress.print = FALSE, closure = NULL)

Arguments

X Compositional data set (matrix or data.frame class).
dl Numeric vector or matrix of detection limits/thresholds. These must be given on the same scale as \( X \).
delta Delta parameter (fraction of the threshold) used in proportions (default = 0.65).
suppress.print Suppress printed feedback (suppress.print = FALSE, default).
closure Closure value used to add a residual part for imputation (see below).

Details

The procedure firstly replaces missing data using the estimated geometric mean based on the observed values and then zeros using \( \delta \times d_l \). The observed components are applied a multiplicative adjustment to preserve the multivariate compositional properties of the samples.

Note: negative values can be generated when unobserved components are a large portion of the composition, which is more likely for missing data (e.g in major chemical elements) and non-closed compositions. A workaround is to add a residual filling the gap up to the closure/total when possible. This is done internally when a value for closure is specified (e.g. closure=10^6 if ppm or closure=100 if percentages). The residual is discarded after imputation.

See \texttt{multRepl} for more details.

Value

A \texttt{data.frame} object containing the imputed compositional data set in the same scale as the original.

             38.09,7.62,23.68,9.70,20.91,0.00),
```

Pigs data set

Description

Count data set consisting of scan sample behavioural observations of a group of 29 sows during a day from 7:30am to 3:30pm, and recorded every 5 minutes (97 times). Six locations were considered: straw bed (BED), half in the straw bed (HALF.BED), dunging passage (PASSAGE), half in the dunging passage (HALF.PASS), feeder (FEEDER) and half in the feeder (HALF.FEED).

Usage

data(Pigs)
Format

A `data.frame` with 29 observations on the following 6 variables.

- BED a numeric vector
- HALF.BED a numeric vector
- PASSAGE a numeric vector
- HALF.PASS a numeric vector
- FEEDER a numeric vector
- HALF.FEED a numeric vector

Source

Data set kindly provided by the Animal Behaviour and Welfare group at Scotland’s Rural College (SRUC), Scotland, UK.

Examples

```r
data(Pigs)
```

`splineKM

Display Kaplan-Meier empirical cumulative distribution function and smoothing spline curve fit

Description

This function shows the empirical cumulative distribution function (ECDF) for left-censored data as estimated by the Kaplan-Meier (KM) method and a cubic smoothing spline fitted to it (KMSS method, see `multKM`).

Usage

```r
splineKM(x, label = NULL, dl = NULL, n.knots = NULL,
        legend.pos = "bottomright",
        ylab = "ECDF", xlab = "Value",
        col.km = "black", lty.km = 1, lwd.km = 1,
        col.sm = "red", lty.sm = 2, lwd.sm = 2, ...)
```

Arguments

- `x` Numerical data vector (`vector` class).
- `label` Unique label (`numeric` or `character`) used to denote left-censored values in `x`.
- `dl` Numeric vector of detection limits/thresholds for each element of `x` (same length as `x`). These must be given on the same scale as `x` (use e.g. 0 for detected data).
- `n.knots` Integer or function giving the number of knots used for fitting a cubic smoothing spline to the KM ECDF (see `smooth.spline` for default value).
legend.pos  Location of the graph legend. Choose one amongst "bottomleft", "bottomright" (default), "topleft" or "topright".

ylab    Title for y-axis.
xlab    Title for x-axis.
col.km   Plotting color for KM ECDF (see base graphical parameters par).
lty.km   Line type for KM ECDF (see base graphical parameters par).
lwd.km   Line width for KM ECDF (see base graphical parameters par).
col.sm   Plotting color for smoothing spline curve.
lty.sm   Line style for smoothing spline curve.
lwd.sm   Line width for smoothing spline curve.
...    Other graphical parameters.

Value

Graphical output.

Examples

data(Water)
data(md1)

# Examine default spline smoothed KM ECDF fit for Potassium and Sulphate
splineKM(Water[,1],label=0,md1[,1])
splineKM(Water[,4],label=0,md1[,4],xlim=c(28,41))

# Reduce to 5 knots for Potassium
splineKM(Water[,1],label=0,md1[,1],n.knots=5)

Water  Water data set

Description

100 simulated samples of a 4-part groundwater composition in percentage subject to multiple limits of detection by component. The associated matrix of limits of detection is stored in md1.

Usage

data(Water)

Format

A data.frame with 100 observations on the following 4 variables.

Potassium  a numeric vector
Arsenic    a numeric vector
Calcium    a numeric vector
Sulphate   a numeric vector
Details

Three limits of detection (0.75, 1 and 1.25) were considered for Potassium, four for Arsenic (1.5, 3, 4 and 5), two for Sulphate (29 and 35) and no one for Calcium. In the case of Sulphate, the detection limit equal to 29 is the minimum value registered for that component. All nondetects coded as 0.

Examples

data(Water)
zPatterns(Water,label=0)

---

zCompositions

Treatment of zeros and nondetects in compositional data sets

Description

Following compositional data analysis principles, this package provides simple and friendly tools to explore and impute zeros, left-censored (such as rounded zeros or values below single or multiple limits of detection; a.k.a nondetects) and missing data; including zero pattern/group-wise data analysis and testing procedures.

Details

Package: zCompositions
Type: Package
Version: 1.3.3-1
Date: 2019-12-07
License: GPL (>= 2)

zPatterns

Find and display patterns of zeros/missing values in a data set

Description

This function summarises the patterns of zero and/or missing values in a data set and returns a vector of pattern numbers.

Usage

zPatterns(X, label = NULL, plot = TRUE,
            axis.labels = c("Component", "Pattern ID"),
            bar.ordered = as.character(c(FALSE,FALSE)),
            bar.colors = c("red3", "red3"), bar.labels = FALSE,
            show.means = FALSE, round.means = 2, cex.means = 1,
type.means = c("cgm","am"),
cell.colors = c("dodgerblue","white"),
cell.labels = c(label, paste("No", label)), cex.axis = 1.1,
grid.color = "black", grid.lty = "dotted",
legend = TRUE, suppress.print = FALSE, ...

Arguments

X       Data set (matrix or data.frame class).
label   Unique label (numeric or character) used to identify zero or unobserved values in X.
plot    Logical value indicating whether a graphical summary of the patterns is produced or not (default plot=TRUE).
axis.labels Vector of axis labels for the table of patterns (format c("x-axis","y-axis").
bar.ordered Vector of logical values to order table of patterns according to frequencies by patterns, component or both; with the first element referring to the patterns and the second to the components (default c(FALSE,FALSE)).
bar.colors Colors for the margin barplots (format c("col.top","col.right").
bar.labels Logical value indicating if labels showing percentages must be added to the margin barplots (default bar.labels=FALSE).
show.means Logical value indicating if mean values by pattern are shown on the graphical summary table (default show.means=FALSE).
round.means When show.means=TRUE, number of decimal places for the mean values shown (2=default).
cex.means When show.means=TRUE, numeric character expansion factor; character size for the mean values shown (1=default).
type.means When show.means=TRUE, statistic used for computing the means. Either compositional geometric mean (type.means=cgm, in percentage units, default) or standard arithmetic mean (type.means=am).
cell.colors Vector of colors for the table cells (format c("col.unobserved","col.observed").
cell.labels Labels for the cells (format c("Unobserved","Observed"), default c(label,paste("No",label))).
cex.axis Axis labels scaling factor relative to default.
grid.color Color of the grid lines (default "black").
grid.lty Style of the grid lines (default "dotted", see lty in par).
legend Logical value indicating if a legend must be included (default legend=TRUE).
suppress.print Suppress printed feedback (default suppress.print=FALSE).
... Other graphical parameters.

Value

Vector (factor type) of pattern IDs corresponding to each row of X.

By default, a summary table is printed showing patterns in the data according to label and some summary statistics: number of zero/missing components by pattern (No.Unobs), pattern frequency
in percentage, percentage zero/missing values by component (column) and overall percentage of zero/missing values in the data set. The symbols + and - indicate, respectively, zero/missing and observed components within each pattern. A graphical version of the summary table is returned including barplots on the margins displaying percentage zero/missing and compositional geometric means by pattern (if show.means=TRUE; expressed in percentage scale). Common arithmetic means can be also shown for the case of ordinary data (type.means="am"), however this is not recommended for compositional data.

The patterns are assigned ID number and by default arranged in the table in the same order as they are found in the data set. The argument bar.ordered can be used to re-arrange the display according to frequencies of patterns, of unobserved values by component or both.

A warning message is shown if zeros or NA values not identified by label are present in the data set. These will be ignored for the graphical display and numerical summaries of patterns, which will be only based on label.

Check out ‘plus’ functions to deal with zeros and missing data simultaneously.

zVarArray

Variation array for grouped data

Description
This function returns overall and separate variation arrays for groups in a compositional data set. Groups can be defined by either zero/unobserved data patterns or by a grouping factor in fully observed zero-free data sets.

Usage
zVarArray(X, label = 0, groups = NULL, suppress.print = FALSE)

Arguments
X
Compositional data set (matrix or data.frame class).
label
Unique label (numeric or character) used to denote zero or unobserved data in X (label = 0, default).
groups
Grouping factor in fully observed zero-free data sets (groups = NULL, default).
suppress.print
Suppress printed feedback (suppress.print = FALSE, default).

Details
This function is mainly aimed to investigate heterogeneous relative variation structures in compositional data sets containing zeros or unobserved values. For each pattern of zero or unobserved values, log-ratio variances (upper triangle of variation matrix) and means (lower triangle of variation matrix) are computed from the available data. Note that (1) NAs are produced for log-ratio variances and means in groups containing less than two observations, and (2) at least two components must be available in each group to compute log-ratios.

The overall estimate is obtained across groups by pairwise deletion. Note that, unlike the ordinary \texttt{var} function, maximum likelihood estimates of the variances are computed. That is, the observed sum of squares is divided by the corresponding number of observations \( n \) and not by \( n-1 \).

Group-wise variation arrays can be obtained from fully observed zero-free data by setting a grouping factor using the argument \texttt{groups}.

Value
List of variation arrays by pattern/group and overall.

\texttt{zPatterns}
Examples

```r
data(Water)
zPatterns(Water, label = 0)
zVarArray(Water)

# From a completed data set

data(mdl) # matrix of limits of detection for Water
Water_multKM <- multKM(Water,label=0, dl=mdl) # nondetects imputation

# Results split by two ficticious groups A and B
zVarArray(Water_multKM, groups=rep(c("A","B"), each=50))
```

<table>
<thead>
<tr>
<th>zVarArrayError</th>
<th>Variation array relative error</th>
</tr>
</thead>
</table>

Description

This function computes squared relative errors of variation arrays per group with respect to the overall variation array based on observed data in a compositional data set. Groups can be defined by either zero/unobserved data patterns or by a grouping factor in fully observed zero-free data sets.

Usage

```r
zVarArrayError(X, label = 0, groups = NULL, breakdown = FALSE, suppress.print = FALSE)
```

Arguments

- **X**: Compositional data set (`matrix` or `data.frame` class).
- **label**: Unique label (`numeric` or `character`) used to denote zero or unobserved data in `X` (label = 0, default).
- **groups**: Grouping factor in fully observed zero-free data sets (`groups = NULL`, default).
- **breakdown**: Logical value. Show results broken down by group (`breakdown = FALSE`, default).
- **suppress.print**: Suppress printed feedback (`suppress.print = FALSE`, default).

Details

Squared relative errors (SRE) are calculated by confronting variation arrays (log-ratio variances and means) obtained per group and the overall variation array based on observed data. Raw SREs are computed for each available pair-wise log-ratio. The weighted version uses the corresponding group sizes to weight raw SREs. Total SRE is obtained as the sum of weighted SREs for each log-ratio. Further details by group are provided by setting `breakdown = TRUE`. 
Value

1. SRE for each log-ratio variance and mean. 2. Weighted SRE for each log-ratio variance and mean. 3. Total SRE across log-ratio variances and means. 4. Percentage contribution of each log-ratio to SRE in log-ratio variances and means. If breakdown = TRUE: 4. SREs per group. 5. Weighted SREs per group. 6. Percentage contribution of each group to total SRE.

# From a completed data set
data(mdl) # matrix of limits of detection for Water
Water_multKM <- multKM(Water,label=0,dl=mdl) # nondetects imputation

# Results split by two ficticious groups A and B
zVarArrayError(Water_multKM,groups=rep(c("A","B"),each=50))

zVarArrayTest

Variation array homogeneity test

Description

This function performs a permutation test of the homogeneity of group-wise and overall variation arrays from all pair-wise log-ratios in a compositional data set. Groups can be defined by either zero/unobserved data patterns or by a grouping factor in fully observed zero-free data sets.

Usage

zVarArrayTest(X, label = 0, groups = NULL, b = 1000)

Arguments

X Compositional data set (matrix or data.frame class).
label Unique label (numeric or character) used to denote zero or unobserved data in X (label = 0, default).
groups Grouping factor in fully observed zero-free data sets (groups = NULL, default).
b Number of bootstrap resamples used (b = 1000, default).
The permutation test of homogeneity is based on total weighted squared relative errors (SRE) reflecting on divergence between group-wise variation arrays and overall (see `zVarArrayError` and `zVarArray` for more details). Note that for groups including less than two observations SRE is set to NA.

Test p-values for log-ratio variances and means.

`zPatterns`, `zVarArray`, `zVarArrayError`

```r
data(Water)
zPatterns(Water, label = 0)
zVarArrayTest(Water)
```
