Package ‘zoo’

April 13, 2017

Version 1.8-0
Date 2017-04-13
Title S3 Infrastructure for Regular and Irregular Time Series (Z's Ordered Observations)
Description An S3 class with methods for totally ordered indexed observations. It is particularly aimed at irregular time series of numeric vectors/matrices and factors. zoo's key design goals are independence of a particular index/date/time class and consistency with ts and base R by providing methods to extend standard generics.
Depends R (>= 2.10.0), stats
Suggests coda, chron, DAAG, fts, ggplot2, mondate, scales, strucchange, timeDate, timeSeries, tis, tseries, xts
Imports utils, graphics, grDevices, lattice (>= 0.20-27)
License GPL-2 | GPL-3
URL http://zoo.R-Forge.R-project.org/
NeedsCompilation yes

aggregate.zoo

Compute Summary Statistics of zoo Objects

Description

Splits a "zoo" object into subsets along a coarser index grid, computes summary statistics for each, and returns the reduced "zoo" object.

Usage

```r
### S3 method for class 'zoo'
aggregate(x, by, FUN = sum, ..., 
    regular = NULL, frequency = NULL, coredata = TRUE)
```
Arguments

x an object of class "zoo".

by index vector of the same length as index(x) which defines aggregation groups and the new index to be associated with each group. If by is a function, then it is applied to index(x) to obtain the aggregation groups.

FUN a function to compute the summary statistics which can be applied to all subsets. Always needs to return a result of fixed length (typically scalar).

... further arguments passed to FUN.

regular logical. Should the aggregated series be coerced to class "zooereg" (if the series is regular)? The default is FALSE for "zoo" series and TRUE for "zooereg" series.

frequency numeric indicating the frequency of the aggregated series (if a "zooereg" series should be returned. The default is to determine the frequency from the data if regular is TRUE. If frequency is specified, it sets regular to TRUE. See examples for illustration.

coredata logical. Should only the coredata(x) be passed to every by group? If set to FALSE the full zoo series is used.

Value

An object of class "zoo" or "zooereg".

Note

The xts package functions endpoints, period.apply to.period, to.weekly, to.monthly, etc., can also directly input and output certain zoo objects and so can be used for aggregation tasks in some cases as well.

See Also

zoo

Examples

```r
## averaging over values in a month:
# x.date is jan 1,3,5,7; feb 9,11,13; mar 15,17,19
x.date <- as.Date(paste(2004, rep(1:4, 4:1), seq(1,20,2), sep = "-")); x.date
x <- zoo(rnorm(12), x.date); x
# coarser dates - jan 1 (4 times), feb 1 (3 times), mar 1 (3 times)
x.date2 <- as.Date(paste(2004, rep(1:4, 4:1), 1, sep = "-")); x.date2
x2 <- aggregate(x, x.date2, mean); x2
# same - uses as.yearmon
x2a <- aggregate(x, as.Date(as.yearmon(time(x))), mean); x2a
# same - uses by function
x2b <- aggregate(x, function(tt) as.Date(as.yearmon(tt)), mean); x2b
# same - uses cut
x2c <- aggregate(x, as.Date(cut(time(x), "month")), mean); x2c
# almost same but times of x2d have yearmon class rather than Date class
x2d <- aggregate(x, as.yearmon, mean); x2d
```
## aggregate.zoo

```r
define a daily time series to a quarterly series
# create zoo series
t <- as.Date("2000-1-1") + 0:300
day <- zoo(t, t)

# function which returns corresponding first "Date" of quarter
first.of.quarter <- function(t) as.Date(as.yeartr(t))

# average z over quarters
# 1. via "yeartr" index (regular)
# 2. via "Date" index (not regular)
qtr1 <- aggregate(day, as.yeartr, mean)
qtr2 <- aggregate(day, first.of.quarter, mean)

# The last one used the first day of the quarter but suppose
# we want the first day of the quarter that exists in the series
# (and the series does not necessarily start on the first day
# of the quarter).
day[!duplicated(as.yeartr(time(day)))]

# This is the same except it uses the last day of the quarter.
# It requires R 2.6.0 which introduced the fromLast= argument.
# Not run:
day[!duplicated(as.yeartr(time(day)), fromLast = TRUE)]

# End(Not run)

# The aggregated series above are of class "zoo" (because day
# was "zoo"). To create a regular series of class "zooreg",
# the frequency can be automatically chosen
zr.qtr1 <- aggregate(day, as.yeartr, mean, regular = TRUE)
# or specified explicitly
zr.qtr2 <- aggregate(day, as.yeartr, mean, frequency = 4)

# aggregate on month and extend to monthly time series
if(require(chron)) {
y <- zoo(matrix(11:15, nrow = 5, ncol = 2), chron(c(15, 20, 80, 300, 110)))
colnames(y) <- c("A", "B")

# aggregate by month using first of month as times for coarser series
# using first day of month as representative time
y2 <- aggregate(y, as.Date(as.yearmon(time(y))), head, 1)

# fill in missing months by merging with an empty series containing
# a complete set of 1st of the months
yrt2 <- range(time(y2))
y0 <- zoo(seq(from = yrt2[1], to = yrt2[2], by = "month"))
```

---

### Notes

- The code demonstrates how to aggregate time series data from a daily to a quarterly frequency, and further to a monthly frequency.
- It includes functions to calculate the first day of a quarter and to aggregate data over quarters.
- The regular series are created using the `zooreg` class with automatic or specified frequency.
- The code also shows how to aggregate data on a monthly basis and extend it to a monthly time series.

---

### Further Reading

- `zoo` package documentation for more advanced time series manipulation.
- `chron` package documentation for handling time series data.

---

### Conclusion

This code snippet provides a practical example of time series aggregation and extension using the `zoo` and `chron` packages in R, which are essential for handling and manipulating time series data.
merge(y2, y0)
}

# given daily series keep only first point in each month at
# day 21 or more
z <- zoo(101:200, as.Date("2000-01-01") + seq(0, length = 100, by = 2))
zz <- z[as.numeric(format(time(z), "%d")== 21]
zz[!duplicated(as.yearmon(time(zz)))]

# same except times are of "yearmon" class
aggregate(zz, as.yearmon, head, 1)

# aggregate POSIXct seconds data every 10 minutes
tt <- seq(10, 2000, 10)
x <- zoo(tt, structure(tt, class = c("POSIXt", "POSIXct")))
aggregate(x, time(x) - as.numeric(time(x)) %% 600, mean)

# aggregate weekly series to a series with frequency of 52 per year
set.seed(1)
z <- zooreg(1:100 + rnorm(100), start = as.Date("2001-01-01"), deltat = 7)

# new.freq() converts dates to a grid of freq points per year
# yd is sequence of dates of firsts of years
# yy is years of the same sequence
# last line interpolates so dates, d, are transformed to year + frac of year
# so first week of 2001 is 2001.0, second week is 2001 + 1/52, third week
# is 2001 + 2/52, etc.
new.freq <- function(d, freq = 52) {
  y <- as.Date(cut(range(d), "years")+c(0, 367)
yd <- seq(y[1], y[2], "year")
  yy <- as.numeric(format(yd, "%Y"))
  floor(freq * approx(yd, yy, xout = d$y) / freq
}

# take last point in each period
aggregate(z, new.freq, tail, 1)

# or, take mean of all points in each
aggregate(z, new.freq, mean)

# example of taking means in the presence of NAs
z.na <- zooreg(c(1:364, NA), start = as.Date("2001-01-01"))
aggregate(z.na, as.yearqtr, mean, na.rm = TRUE)

# Find the sd of all days that lie in any Jan, all days that lie in
# any Feb, ..., all days that lie in any Dec (i.e. output is vector with
# 12 components)
aggregate(z, format(time(z), "%m"), sd)

---

Coercion from and to zoo
Description

Methods for coercing "zoo" objects to other classes and a generic function `as.zoo` for coercing objects to class "zoo".

Usage

```r
as.zoo(x, ...)
```

Arguments

- `x` an object,
- `...` further arguments passed to `zoo` when the return object is created.

Details

`as.zoo` currently has a default method and methods for `ts, fts, irts, mcmc, tis, xts` objects (and `zoo` objects themselves).

Methods for coercing objects of class "zoo" to other classes currently include: `as.ts, as.matrix, as.vector, as.data.frame, as.list` (the latter also being available for "ts" objects).

In the conversion between zoo and ts, the `zooreg` class is always used.

Value

`as.zoo` returns a `zoo` object.

See Also

`zoo, zooreg, ts, irts, tis, fts, mcmc, xts`.

Examples

```r
## coercion to zoo:
## default method
as.zoo(rnorm(5))
## method for "ts" objects
as.zoo(ts(rnorm(5), start = 1981, freq = 12))

## coercion from zoo:
x.date <- as.POSIXct(paste("2003-", rep(1:4, 4:1), "-", sample(1:28, 10, replace = TRUE), sep = ""))
x <- zoo(matrix(rnorm(24), ncol = 2), x.date)
as.matrix(x)
as.vector(x)
as.data.frame(x)
as.list(x)
```
coredata  Extracting/Replacing the Core Data of Objects

Description

Generic functions for extracting the core data contained in a (more complex) object and replacing it.

Usage

coredata(x, ...)  
coredata(x) <- value

Arguments

x  
an object.

...  
further arguments passed to methods.

value  
a suitable value object for use with x.

Value

In zoo, there are currently coredata methods for time series objects of class "zoo", "ts", "irts", "irts", all of which strip off the index/time attributes and return only the observations. The are also corresponding replacement methods for these classes.

See Also

zoo

Examples

x.date <- as.Date(paste(2003, rep(1:4, 4:1), seq(1,20,2), sep = "-"))  
x <- zoo(matrix(rnorm(20), ncol = 2), x.date)

## the full time series
x

## and only matrix of observations
coredata(x)

## change the observations
coredata(x) <- matrix(1:20, ncol = 2)
x
frequency<-  Replacing the Index of Objects

Description

Generic function for replacing the frequency of an object.

Usage

frequency(x) <- value

Arguments

x  an object.
value  a frequency.

Details

frequency<- is a generic function for replacing (or assigning) the frequency of an object. Currently, there is a "zooereg" and a "zoo" method. In both cases, the value is assigned to the "frequency" of the object if it complies with the index(x).

See Also

zooreg, index

Examples

z <- zooereg(1:5)
z
as.ts(z)
frequency(z) <- 3
z
as.ts(z)

ggplot2.zoo  Convenience Functions for Plotting zoo Objects with ggplot2

Description

fortify.zoo takes a zoo object and converts it into a data frame (intended for ggplot2). autoplot.zoo takes a zoo object and returns a ggplot2 object. It essentially uses the mapping aes(x = Time, y = Value, group = Series) and adds colour = Series, linetype = Series, shape = Series in the case of a multivariate series with facets = NULL.
Usage

```r
## S3 method for class 'zoo'
autoplot(object, geom = "line", facets, ...)
## S3 method for class 'zoo'
fortify(model, data, melt = FALSE, ...)

facet_free(facets = Series ~ ., margins = FALSE, scales = "free_y", ...)

yearmon_trans(format = "%b %Y", n = 5)
scale_x_yearmon(..., format = "%b %Y", n = 5)
scale_y_yearmon(..., format = "%b %Y", n = 5)

yearqtr_trans(format = "%Y-%q", n = 5)
scale_x_yearqtr(..., format = "%Y-%q", n = 5)
scale_y_yearqtr(..., format = "%Y-%q", n = 5)
```

Arguments

- `object`: an object of class "zoo".
- `geom`: character specifying which `geom` to use in `qplot`.
- `facets`: specification of facets for `qplot`. The default in the autoplot method is to use `facets = NULL` for univariate series and `facets = Series ~ .` for multivariate series.
- `...`: further arguments passed to `qplot` for autoplot (and not used for fortify).
- `model`: an object of class "zoo" to be converted to a "data.frame".
- `data`: not used (required by generic `fortify` method).
- `melt`: Should the resulting data frame be in long format (`melt = TRUE`) or wide format (`melt = FALSE`).
- `margins`: As in `facet_grid`.
- `scales`: As in `facet_grid` except it defaults to "free_y".
- `format`: A format acceptable to `format.yearmon` or `format.yearqtr`.
- `n`: Approximate number of axis ticks.

Details

Convenience interface for visualizing zoo objects with ggplot2. `autoplot.zoo` uses `fortify.zoo` (with `melt = TRUE`) to convert the zoo object into a data frame and then uses a suitable `aes()` mapping to visualize the series.

Value

- `fortify.zoo` returns a `data.frame` either in long format (`melt = TRUE`) or in wide format (`melt = FALSE`). The long format has three columns: the time `Index`, a factor indicating the `Series`, and the corresponding `Value`. The wide format simply has the time `Index` plus all columns of `coredata(model)`.
- `autoplot.zoo` returns a `ggplot` object.

**index**

**Extracting/Replacing the Index of Objects**

**Description**

Generic functions for extracting the index of an object and replacing it.

**Usage**

```
index(x, ...) 
index(x) <- value 
```

**Arguments**

- `x` an object.
- `...` further arguments passed to methods.
- `value` an ordered vector of the same length as the "index" attribute of `x`.

**Details**

`index` is a generic function for extracting the index of objects, currently it has a default method and a method for `zoo` objects which is the same as the `time` method for `zoo` objects. Another pair of generic functions provides replacing the index or time attribute. Methods are available for "zoo" objects only, see examples below.

The start and end of the index/time can be queried by using the methods of `start` and `end`.

**See Also**

`time`, `zoo`
is.regular

Check Regularity of a Series

Description

is.regular is a regular function for checking whether a series of ordered observations has an underlying regularity or is even strictly regular.

Usage

is.regular(x, strict = FALSE)

Arguments

x an object (representing a series of ordered observations).
strict logical. Should strict regularity be checked? See details.
Details

A time series can either be irregular (unequally spaced), strictly regular (equally spaced) or have an underlying regularity, i.e., be created from a regular series by omitting some observations. Here, the latter property is called regular. Consequently, regularity follows from strict regularity but not vice versa.

`is.regular` is a generic function for checking regularity (default) or strict regularity. Currently, it has methods for "ts" objects (which are always strictly regular), "zooreg" objects (which are at least regular), "zoo" objects (which can be either irregular, regular or even strictly regular) and a default method. The latter coerces x to "zoo" before checking its regularity.

Value

A logical is returned indicating whether x is (strictly) regular.

See Also

`zooreg`, `zoo`

Examples

```R
## checking of a strictly regular zoo series
z <- zoo(1:10, seq(2000, 2002.25, by = 0.25), frequency = 4)

z

class(z)
frequency(z) ## extraction of frequency attribute
is.regular(z)
is.regular(z, strict = TRUE)
## by omitting observations, the series is not strictly regular
is.regular(z[-3])
is.regular(z[-3], strict = TRUE)

## checking of a plain zoo series without frequency attribute
## which is in fact regular
z <- zoo(1:10, seq(2000, 2002.25, by = 0.25))

z
class(z)
frequency(z) ## data driven computation of frequency
is.regular(z)
is.regular(z, strict = TRUE)
## by omitting observations, the series is not strictly regular
is.regular(z[-3])
is.regular(z[-3], strict = TRUE)

## checking of an irregular zoo series
z <- zoo(1:10, rnorm(10))

z
class(z)
frequency(z) ## attempt of data-driven frequency computation
is.regular(z)
is.regular(z, strict = TRUE)
```
Description

Methods for computing lags and differences of "zoo" objects.

Usage

```r
## S3 method for class 'zoo'
lag(x, k = 1, na.pad = FALSE, ...)
## S3 method for class 'zoo'
diff(x, lag = 1, differences = 1, arithmetic = TRUE, na.pad = FALSE, ...)
```

Arguments

- `x` a "zoo" object.
- `k, lag` For `lag` the number of lags (in units of observations). Note the sign of `k` behaves as in `lag`. For `diff` it is the number of backward lags used (or if negative the number of forward lags).
- `differences` an integer indicating the order of the difference.
- `arithmetic` logical. Should arithmetic (or geometric) differences be computed?
- `na.pad` logical. If TRUE it adds any times that would not otherwise have been in the result with a value of NA. If FALSE those times are dropped.
- `...` currently not used.

Details

These methods for "zoo" objects behave analogously to the default methods. The only additional arguments are `arithmetic` in `diff` `na.pad` in `lag`, `zoo` which can also be specified in `diff.zoo` as part of the dots. Also, "k" can be a vector of lags in which case the names of "k", if any, are used in naming the result.

Value

The lagged or differenced "zoo" object.

Note

Note the sign of `k`: a series lagged by a positive `k` is shifted *earlier* in time.

`lag.zoo` and `lag.zoo.reg` can give different results. For a lag of 1 `lag.zoo` moves points to the adjacent time point whereas `lag.zoo.reg` moves the time by `deltat`. This implies that a point in a `zoo` series cannot be lagged to a time point that is not already in the series whereas this is possible for a `zoo.reg` series.
make.par.list

See Also

zoo, lag, diff

Examples

x <- zoo(1:21)

lag(x, k = 1)
lag(x, k = -1)
# this pairs each value of x with the next or future value
merge(x, lag1 = lag(x, k=1))
diff(x^3)
diff(x^3, -1)
diff(x^3, na.pad = TRUE)

Description

Process parameters so that a list of parameter specifications is returned (used by plot.zoo and xyplot.zoo).

Usage

make.par.list(nams, x, n, m, def, recycle = sum(unnamed) > 0)

Arguments

nams character vector with names of variables.
x list or vector of parameter specifications, see details.
n numeric, number of rows.
m numeric, number of columns. (Only determines whether m is 1 or greater than 1.
def default parameter value.
recycle logical. If TRUE recycle columns to provide unspecified ones. If FALSE use def to provide unspecified ones. This only applies to entire columns. Within columns recycling is always done regardless of how recycle is set. Defaults to TRUE if there is at least one unnamed variable and defaults to FALSE if there are only named variables in x.

Details

This function is currently intended for internal use. It is currently used by plot.zoo and xyplot.zoo but might also be used in the future to create additional new plotting routines. It creates a new list which uses the named variables from x and then assigns the unnamed in order. For the remaining variables assign them the default value if !recycle or recycle the unnamed variables if recycle.
Value

A list of parameters, see details.

Examples

```r
make.par.list(letters[1:5], 1:5, 3, 5)
suppressWarnings( make.par.list(letters[1:5], 1:4, 3, 5, 99) )
make.par.list(letters[1:5], c(d=3), 3, 5, 99)
make.par.list(letters[1:5], list(d=1:2, 99), 3, 5)
make.par.list(letters[1:5], list(d=1:2, 99, 100), 3, 5)
```

---

Description

MATCH is a generic function for value matching.

Usage

```r
MATCH(x, table, nomatch = NA, ...) # S3 method for class 'times'
MATCH(x, table, nomatch = NA, units = "sec", eps = 1e-10, ...)
```

Arguments

- `x`: an object.
- `table`: the values to be matched against.
- `nomatch`: the value to be returned in the case when no match is found. Note that it is coerced to integer.
- `units`: See `trunc.times`.
- `eps`: See `trunc.times`.
- `...`: further arguments to be passed to methods.

Details

MATCH is a new generic function which aims at providing the functionality of the non-generic base function `match` for arbitrary objects. Currently, there is only a default method which simply calls `match`.

MATCH.times is used for chron objects. `x` will match any time in `table` less than `units` away.

See Also

- `match`

Examples

```r
MATCH(1:5, 2:3)
```
**merge.zoo**

*Merge Two or More zoo Objects*

**Description**

Merge two zoo objects by common indexes (times), or do other versions of database *join* operations.

**Usage**

```r
## S3 method for class 'zoo'
merge(..., all = TRUE, fill = NA, suffixes = NULL,
       check.names = FALSE, retclass = c("zoo", "list", "data.frame"),
       drop = TRUE)
```

**Arguments**

- **...**: two or more objects, usually of class "zoo".
- **all**: logical vector having the same length as the number of "zoo" objects to be merged (otherwise expanded).
- **fill**: an element for filling gaps in merged "zoo" objects (if any).
- **suffixes**: character vector of the same length as the number of "zoo" objects specifying the suffixes to be used for making the merged column names unique.
- **check.names**: See `link{read.table}`.
- **retclass**: character that specifies the class of the returned result. It can be "zoo" (the default), "list" or NULL. For details see below.
- **drop**: logical. If a "zoo" object without observations is merged with a one-dimensional "zoo" object (vector or 1-column matrix), should the result be a vector (drop = TRUE) or a 1-column matrix (drop = FALSE)? The former is the default in the `merge` method, the latter in the `cbind` method.

**Details**

The `merge` method for "zoo" objects combines the columns of several objects along the union of the dates for `all = TRUE`, the default, or the intersection of their dates for `all = FALSE` filling up the created gaps (if any) with the `fill` pattern.

The first argument must be a zoo object. If any of the remaining arguments are plain vectors or matrices with the same length or number of rows as the first argument then such arguments are coerced to "zoo" using `as.zoo`. If they are plain but have length 1 then they are merged after all non-scalars such that their column is filled with the value of the scalar.

`all` can be a vector of the same length as the number of "zoo" objects to merged (if not, it is expanded): All indexes (times) of the objects corresponding to TRUE are included, for those corresponding to FALSE only the indexes present in all objects are included. This allows intersection, union and left and right joins to be expressed.

If `retclass` is "zoo" (the default) a single merged "zoo" object is returned. If it is set to "list" a list of "zoo" objects is returned. If `retclass = NULL` then instead of returning a value it updates
each argument (if it is a variable rather than an expression) in place so as to extend or reduce it to use the common index vector.

The indexes of different "zoo" objects can be of different classes and are coerced to one class in the resulting object (with a warning).

The default `cbind` method is essentially the default `merge` method, but does not support the `retclass` argument. The `rbind` method combines the dates of the "zoo" objects (duplicate dates are not allowed) and combines the rows of the objects. Furthermore, the `c` method is identical to the `rbind` method.

**Value**

An object of class "zoo" if `retclass="zoo"`, an object of class "list" if `retclass="list"` or modified arguments as explained above if `retclass=NULL`. If the result is an object of class "zoo" then its frequency is the common frequency of its `zoo` arguments, if they have a common frequency.

**See Also**

`zoo`

**Examples**

```R
## simple merging
x$date <- as.Date(paste(2003, 02, c(1, 3, 7, 9, 14), sep = "-"))
x <- zoo(rnorm(5), x$date)

y1 <- zoo(matrix(1:10, ncol = 2), 1:5)
y2 <- zoo(matrix(rnorm(10), ncol = 2), 3:7)

## using arguments 'fill' and 'suffixes'
merge(y1, y2, all = FALSE)
merge(y1, y2, all = FALSE, suffixes = c("a", "b"))
merge(y1, y2, all = TRUE)
merge(y1, y2, all = TRUE, fill = 0)

## if different index classes are merged, as in
## the next merge example then ## a warning is issued and
## the indexes are coerced.
## It is up to the user to ensure that the result makes sense.
merge(x, y1, y2, all = TRUE)

## extend an irregular series to a regular one:
# create a constant series
z <- zoo(1, seq(4)[-2])
# create a 0 dimensional zoo series
z0 <- zoo(), 1:4)
# do the extension
merge(z, z0)
# same but with zero fill
merge(z, z0, fill = 0)
merge(z, coredata(z), 1)
```
### merge multiple series represented in a long form data frame
### into a multivariate zoo series and plot, one series for each site.
### Additional examples can be found here:
###
m <- 5  # no of years
n <- 6  # no of sites
sites <- LETTERS[1:n]
set.seed(1)
DF <- data.frame(sites, year = 2000 + 1:m, data = rnorm(m*n))
tozoo <- function(x) zoo(x$data, x$year)
Data <- do.call(merge, lapply(split(DF, DF$sites), tozoo))
plot(Data, screen = 1, col = 1:n, pch = 1:n, type = "o", xlab = "")
legend("bottomleft", legend = sites, lty = 1, pch = 1:n, col = 1:n)

### for each index value in x merge it with the closest index value in y
### but retaining x's times.
x <- zoo(1:3, as.Date(c("1992-12-13", "1997-05-12", "1997-07-13")))
f <- function(u) which.min(abs(as.numeric(index(y)) - as.numeric(u)))
ix <- sapply(index(x), f)
cbind(x, y = coredata(y)[ix])

### this merges each element of x with the closest time point in y at or
### after x's time point (whereas in previous example it could be before
### or after)
window(na.locf(merge(x, y), fromLast = TRUE), index(x))

---

### na.aggregate

#### Replace NA by Aggregation

**Description**

Generic function for replacing each NA with aggregated values. This allows imputing by the overall mean, by monthly means, etc.

**Usage**

```r
na.aggregate(object, ...)
```

# Default S3 method:
```r
na.aggregate(object, by = 1, ..., FUN = mean,
        na.rm = FALSE, maxgap = Inf)
```
Arguments

object  an object.
by      a grouping variable corresponding to object, or a function to be applied to
time(object) to generate the groups.
...    further arguments passed to by if by is a function.
FUN    function to apply to the non-missing values in each group defined by by.
a. rm   logical. Should any remaining NAs be removed?
maxgap maximum number of consecutive NAs to fill. Any longer gaps will be left un-

Value

An object in which each NA in the input object is replaced by the mean (or other function) of its
group, defined by by. This is done for each series in a multi-column object. Common choices for
the aggregation group are a year, a month, all calendar months, etc.

If a group has no non-missing values, the default aggregation function mean will return NaN. Specify
a. rm = TRUE to omit such remaining missing values.

zoo

Examples

z <- zoo(c(1, NA, 3:9),
  c(as.Date("2010-01-01") + 0:2,
    as.Date("2010-02-01") + 0:2,
    as.Date("2011-01-01") + 0:2))
## overall mean
na.aggregate(z)
## group by months
na.aggregate(z, as.yearmon)
## group by calendar months
na.aggregate(z, months)
## group by years
na.aggregate(z, format, "%Y")

na.approx Replace NA by Interpolation

Description

Generic functions for replacing each NA with interpolated values.
Usage

na.approx(object, ...)  
## S3 method for class 'zoo'
na.approx(object, x = index(object), xout, ..., na.rm = TRUE, along)
## S3 method for class 'zooreg'
na.approx(object, ...)
## S3 method for class 'ts'
na.approx(object, ...)
## Default S3 method:
na.approx(object, x = index(object), xout, ..., na.rm = TRUE, maxgap = Inf, along)

na.spline(object, ...)  
## S3 method for class 'zoo'
na.spline(object, x = index(object), xout, ..., na.rm = TRUE, along)
## S3 method for class 'zooreg'
na.spline(object, ...)
## S3 method for class 'ts'
na.spline(object, ...)
## Default S3 method:
na.spline(object, x = index(object), xout, ..., na.rm = TRUE, maxgap = Inf, along)

Arguments

- **object**: object in which NAs are to be replaced
- **x, xout**: Variables to be used for interpolation as in approx.
- **na.rm**: logical. If the result of the (spline) interpolation still results in NAs, should these be removed?
- **maxgap**: maximum number of consecutive NAs to fill. Any longer gaps will be left unchanged. Note that all methods listed above can accept maxgap as it is ultimately passed to the default method.
- **along**: deprecated.
- **...**: further arguments passed to methods. The n argument of approx is currently not supported.

Details

Missing values (NAs) are replaced by linear interpolation via approx or cubic spline interpolation via spline, respectively.

It can also be used for series disaggregation by specifying xout.

By default the index associated with object is used for interpolation. Note, that if this calls index.default this gives an equidistant spacing 1:NROW(object). If object is a matrix or data.frame, the interpolation is done separately for each column.

If obj is a plain vector then na.approx(obj, x, y, xout, ...) returns approx(x = x[!na], y = coredata(obj)[!na], (where na indicates observations with NA) such that xout defaults to x. Note that if there are less than two non-NAs then approx() cannot be applied and thus no NAs can be replaced.
If `obj` is a `zoo`, `zooreg` or `ts` object its coredata value is processed as described and its time index is `xout` if specified and `index(obj)` otherwise. If `obj` is two dimensional then the above is applied to each column separately. For examples, see below.

If `obj` has more than one column, the above strategy is applied to each column.

**Value**

An object of similar structure as `object` with NAs replaced by interpolation. For `na.approx` only the internal NAs are replaced and leading or trailing NAs are omitted if `na.rm = TRUE` or not replaced if `na.rm = FALSE`.

**See Also**

`zoo`, `approx`, `na.contiguous`, `na.locf`, `na.omit`, `na.trim`, `spline`, `stinterp`

**Examples**

```r
z <- zoo(c(2, NA, 1, 4, 5, 2), c(1, 3, 4, 6, 7, 8))

## use underlying time scale for interpolation
na.approx(z)

## use equidistant spacing
na.approx(z, 1:6)

# with and without `na.rm = FALSE`
zz <- c(NA, 9, 3, NA, 3, 2)
na.approx(zz, na.rm = FALSE)
na.approx(zz)

d0 <- as.Date("2000-01-01")
z <- zoo(c(11, NA, 13, NA, 15, NA), d0 + 1:6)

# NA fill, drop or keep leading/trailing NAs
na.approx(z)
na.approx(z, na.rm = FALSE)

# extrapolate to point outside of range of time points
# (a) drop NA, (b) keep NA, (c) extrapolate using rule = 2 from approx()
na.approx(z, xout = d0 + 7)
na.approx(z, xout = d0 + 7, na.rm = FALSE)
na.approx(z, xout = d0 + 7, rule = 2)

# use splines - extrapolation handled differently
z <- zoo(c(11, NA, 13, NA, 15, NA), d0 + 1:6)
na.spline(z)
na.spline(z, na.rm = FALSE)
na.spline(z, xout = d0 + 1:6)
na.spline(z, xout = d0 + 2:5)
na.spline(z, xout = d0 + 7)
na.spline(z, xout = d0 + 7, na.rm = FALSE)
```
## na.fill

*Fill NA or specified positions.*

### Description

Generic function for filling NA values or specified positions.

### Usage

```r
aplication
na.fill(object, fill, ...)  
## S3 method for class 'ts'
na.fill(object, fill, ix, ...)
```
## S3 method for class 'zoo'
na.fill(object, fill, ix, ...)

## Default S3 method:
na.fill(object, fill, ix, ...)

### Arguments

- **object**: an object.
- **fill**: a three component list or a vector that is coerced to a list. Shorter objects are recycled. The three components represent the fill value to the left of the data, within the interior of the data and to the right of the data, respectively. The value of any component may be the keyword "extend" to indicate repetition of the leftmost or rightmost non-NA value or linear interpolation in the interior. NULL means that items are dropped rather than filled.
- **ix**: logical. Should be the same length as the number of time points. Indicates which time points not to fill. This defaults to the non-NA values.
- **...**: further arguments passed to methods.

### Details

Fill NA or indicated values.

### See Also

- `na.approx`

### Examples

```r
z <- zoo(c(NA, 2, NA, 1, 4, 5, 2, NA))
na.fill(z, "extend")
na.fill(z, c("extend", NA))
na.fill(z, -(1:3))
na.fill(z, list(NA, NULL, NA))
```

---

### Description

Generic function for replacing each NA with the most recent non-NA prior to it.
**na.locf**

Usage

```r
na.locf(object, na.rm = TRUE, ...)  
# Default S3 method:  
na.locf(object, na.rm = TRUE, fromLast, rev,  
   maxgap = Inf, rule = 2, ...)  

na.locf0(object, fromLast = FALSE, maxgap = Inf, coredata = NULL)
```

Arguments

- **object**: an object.
- **na.rm**: logical. Should leading NAs be removed?
- **fromLast**: logical. Causes observations to be carried backward rather than forward. Default is `FALSE`. With a value of `TRUE` this corresponds to NOCB (next observation carried backward). It is not supported if `x` or `xout` is specified.
- **rev**: Use fromLast instead. This argument will be eliminated in the future in favor of fromLast.
- **maxgap**: Runs of more than `maxgap` NAs are retained, other NAs are removed and the last occurrence in the resulting series prior to each time point in `xout` is used as that time point’s output value. (If `xout` is not specified this reduces to retaining runs of more than `maxgap` NAs while filling other NAs with the last occurrence of a non-NA.)
- **rule**: See `approx`.
- **...**: further arguments passed to methods.
- **coredata**: logical. Should LOCF be applied to the core data of a (time series) object and then assigned to the original object again? By default, this strategy is applied to time series classes (e.g., `ts`, `zoo`, `xts`, etc.) where it preserves the time index.

Value

An object in which each NA in the input object is replaced by the most recent non-NA prior to it. If there are no earlier non-NAs then the NA is omitted (if `na.rm = TRUE`) or it is not replaced (if `na.rm = FALSE`).

The arguments `x` and `xout` can be used in which case they have the same meaning as in `approx`.

Note that if a multi-column zoo object has a column entirely composed of NA then with `na.rm = TRUE`, the default, the above implies that the resulting object will have zero rows. Use `na.rm = FALSE` to preserve the NA values instead.

The function `na.locf0` is the workhorse function underlying the default `na.locf` method. It has more limited capabilities but is faster for the special cases it covers. Implicitly, it uses `na.rm=FALSE`.

az <- zoo(1:6)

bz <- zoo(c(2,NA,1,4,5,2))
na.locf(bz)
na.locf(bz, fromLast = TRUE)

cz <- zoo(c(NA,9,3,2,3,2))
aa.locf(cz)

# generate and fill in missing dates
z <- zoo(c(0.007306621, 0.007659846, 0.007681013, 0.007817548, 0.007847579, 0.007867313),
as.Date(c("1993-01-01", "1993-01-09", "1993-01-16", "1993-01-23", "1993-01-30", "1993-02-06")))
g <- seq(start(z), end(z), "day")
aa.locf(z, xout = g)

# similar but use a 2 second grid
g <- seq(start(z), end(z), by = "2 sec")
aa.locf(z, xout = g)

## get 5th of every month or most recent date prior to 5th if 5th missing.
## Result has index of the date actually used.
z <- zoo(c(1311.56, 1309.04, 1295.5, 1296.6, 1286.57, 1288.12, 1289.12, 1289.12, 1285.33, 1307.65, 1309.93, 1311.46, 1311.28, 1308.11, 1301.74, 1305.41, 1309.72, 1310.61, 1305.19, 1313.21, 1307.85, 1312.25, 1325.76), as.Date(c(13242, 13244, 13245, 13248, 13249, 13250, 13251, 13252, 13255, 13256, 13257, 13258, 13259, 13262, 13263, 13264, 13265, 13266, 13269, 13270, 13271, 13272, 13274)))

# z.na is same as z but with missing days added (with NAs)
# It is formed by merging z with a zero with series having all the dates.
rng <- range(time(z))
z.na <- merge(z, zoo(, seq(rng[1], rng[2], by = "day")))

# use na.locf to bring values forward picking off 5th of month
na.locf(z.na)[as.POSIXlt(time(z.na))$mday == 5]

## this is the same as the last one except instead of always using the
## 5th of month in the result we show the date actually used

# idx has NAs wherever z.na does but has 1, 2, 3, ... instead of
```
# z.na's data values (so idx can be used for indexing)
idx <- coredata( na.locf(seq_along(z.na) + (0 * z.na)) )

# pick off those elements of z.na that correspond to 5th
z.na[idx[as.POSIXlt(time(z.na))$mday == 5]]

## only fill single-day gaps
merge(z.na, filled1 = na.locf(z.na, maxgap = 1))

## fill NAs in first column by inflating the most recent non-NA
## by the growth in second column. Note that elements of x-x
## are NA if the corresponding element of x is NA and zero else
m <- zoo(cbind(c(1, 2, NA, NA, 5, NA, NA), seq(7)^2), as.Date(1:7))

r <- na.locf(m[,1]) * m[,2] / na.locf(m[,2] + (m[,1]-m[,1]))
cbind(V1 = r, V2 = m[,2])

## repeat a quarterly value every month
## preserving NAs
zq <- zoo(c(1, NA, 3, 4), as.yearqtr(2000) + 0:3/4)
tt <- as.yearmon(start(zq)) + seq(0, len = 3 * length(zq))/12
na.locf(zq, xout = tt, maxgap = 0)

---

**na.StructTS**

*Fill NA or specified positions.*

### Description

Generic function for filling NA values using seasonal Kalman filter.

### Usage

`na.StructTS(object, ...)`

## S3 method for class 'ts'
`na.StructTS(object, ..., na.rm = FALSE, maxgap = Inf)`

## S3 method for class 'zoo'
`na.StructTS(object, ..., na.rm = FALSE, maxgap = Inf)`

### Arguments

- `object` an object.
- `...` other arguments passed to methods.
- `na.rm` logical. Whether to remove end portions or fill them with NA.
maxgap

Runs of more than maxgap NAs are retained, other NAs are removed and the last occurrence in the resulting series prior to each time point in xout is used as that time point’s output value.

Details

Interpolate with seasonal Kalman filter. The input object should have a frequency. It is assumed the cycle length is 1.

Examples

# examples of na.trim
x <- zoo(c(1, 4, 6), c(2, 4, 6))
xx <- zoo(matrix(c(1, 4, 6, NA, 5, 7), 3), c(2, 4, 6))
na.trim(x)
na.trim(xx)

# using na.trim for alignment
# cal defines the legal dates
# all dates within the date range of x should be present
cal <- zoo(c(1, 2, 3, 6, 7))
x <- zoo(c(12, 16), c(2, 6))
na.trim(merge(x, cal))

ORDER

Ordering Permutation

Description

ORDER is a generic function for computing ordering permutations.

Usage

ORDER(x, ...)
## Default S3 method:
ORDER(x, ..., na.last = TRUE, decreasing = FALSE)

Arguments

x an object.

... further arguments to be passed to methods.

na.last for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed.

decreasing logical. Should the sort order be increasing or decreasing?
plot.zoo

Details

ORDER is a new generic function which aims at providing the functionality of the non-generic base function \texttt{order} for arbitrary objects. Currently, there is only a default method which simply calls \texttt{order}. For objects (more precisely if \texttt{is.object} is \texttt{TRUE}) \texttt{ORDER} leverages the generic \texttt{xtfrm}. Thus, to assure ordering works, one can supply either a method to \texttt{xtfrm} or to \texttt{ORDER} (or both).

See Also

\texttt{order}

Examples

ORDER(rnorm(5))

Description

Plotting method for objects of class "zoo".

Usage

```r
## S3 method for class 'zoo'
plot(x, y = NULL, screens, plot.type,
    panel = lines, xlab = "Index", ylab = NULL, main = NULL,
    xlim = NULL, ylim = NULL, xy.labels = FALSE, xy.lines = NULL,
    xax.flip = FALSE, oma = c(6, 0, 5, 0),
    mar = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
    col = 1, lty = 1, lwd = 1, pch = 1, type = "1", log = "",
    nc, widths = 1, heights = 1, ...)  
## S3 method for class 'zoo'
lines(x, y = NULL, type = "l", ...)  
## S3 method for class 'zoo'
points(x, y = NULL, type = "p", ...)
```

Arguments

- \texttt{x} an object of class "zoo".
- \texttt{y} an object of class "zoo". If \texttt{y} is \texttt{NULL} (the default) a time series plot of \texttt{x} is produced, otherwise if both \texttt{x} and \texttt{y} are univariate "zoo" series, a scatter plot of \texttt{y} versus \texttt{x} is produced.
- \texttt{screens} factor (or coerced to factor) whose levels specify which graph each series is to be plotted in. \texttt{screens}=\texttt{c(1,2,1)} would plot series 1, 2 and 3 in graphs 1, 2 and 1. If not specified then 1 is used if \texttt{plot.type}="single" and \texttt{seq_len(ncol(x))} otherwise.
plot.type for multivariate zoo objects, "multiple" plots the series on multiple plots and "single" superimposes them on a single plot. Default is "single" if screens has only one level and "multiple" otherwise. If neither screens nor plot.type is specified then "single" is used if there is one series and "multiple" otherwise. This option is provided for back compatibility. Usually screens is used instead.

panel a function(x, y, col, lty, ...) which gives the action to be carried out in each panel of the display for plot.type = "multiple".

ylim if plot.type = "multiple" then it can be a list of y axis limits. If not a list each graph has the same limits. If any list element is not a pair then its range is used instead. If plot.type = "single" then it is as in plot.

xy.labels logical, indicating if text labels should be used in the scatter plot, or character, supplying a vector of labels to be used.

xy.lines logical, indicating if lines should be drawn in the scatter plot. Defaults to the value of xy.labels if that is logical, otherwise to FALSE.

yax.flip logical, indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when type = "multiple".

xlab, ylab, main, xlim, oma, mar graphical arguments, see par.

col, lty, lwd, pch, type graphical arguments that can be vectors or (named) lists. See the details for more information.

log specification of log scales as "x", "y" or "xy".

nc the number of columns to use when plot.type = "multiple". Defaults to 1 for up to 4 series, otherwise to 2.

widths, heights widths and heights for individual graphs, see layout.

... additional graphical arguments.

Details

The methods for plot and lines are very similar to the corresponding ts methods. However, the handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., list(A = c(1,2), c(3,4)) in which c(3, 4) is the default value and c(1, 2) the value only for series A. The screens argument can be specified in a similar way. If plot.type and screens conflict then multiple plots will be assumed. Also see the examples.

In the case of a custom panel the panel can reference parent.frame$panel.number in order to determine which frame the panel is being called from. See examples.

par(mfrow=...) and Axis can be used in conjunction with single panel plots in the same way as with other classic graphics.

For multi-panel graphics, plot.zoo takes over the layout so par(mfrow=...) cannot be used. Axis can be used within the panels themselves but not outside the panel. See examples.

In addition to classical time series line plots, there is also a simple barplot method for "zoo" series.

**Description**

`read.zoo` and `write.zoo` are convenience functions for reading and writing "zoo" series from/to text files. They are convenience interfaces to `read.table` and `write.table`, respectively. To employ `read.csv`, `read.csv2`, `read.delim`, `read.delim2` instead of `read.table` additional functions `read.csv.zoo` etc. are provided.

**Usage**

```r
read.zoo(file, format = "", tz = "", FUN = NULL,
  regular = FALSE, index.column = 1, drop = TRUE, FUN2 = NULL,
  split = NULL, aggregate = FALSE, ..., text)

write.zoo(x, file = "", index.name = "Index", row.names = FALSE, col.names = NULL, ...)

read.csv.zoo(file, format = "", tz = "", FUN = NULL,
  regular = FALSE, index.column = 1, drop = TRUE, FUN2 = NULL,
  split = NULL, aggregate = FALSE, ...) read.csv2.zoo(file, format = "", tz = "", FUN = NULL,
  regular = FALSE, index.column = 1, drop = TRUE, FUN2 = NULL,
  split = NULL, aggregate = FALSE, ...) read.delim.zoo(file, format = "", tz = "", FUN = NULL,
  regular = FALSE, index.column = 1, drop = TRUE, FUN2 = NULL,
  split = NULL, aggregate = FALSE, ...) read.delim2.zoo(file, format = "", tz = "", FUN = NULL,
  regular = FALSE, index.column = 1, drop = TRUE, FUN2 = NULL,
  split = NULL, aggregate = FALSE, ...)
```

```r
lty = list("spinbox", init = 1, from = 0, to = 6, increment = 1, width = 5)
)
z <- zoo(rnorm(25))
tkexamp(plot(z), tke.test1, plotloc = "top")

## End(Not run)

# setting ylim on a multi-panel plot - 2nd panel y axis range is 1-50
data("anscombe", package = "datasets")
ans6 <- zoo(anscombe[, 1:6])
screens <- c(1, 1, 2, 2, 3, 3)
ylim <- unname(tapply(as.list(ans6), screens, range))
ylim[2] <- 1:50 # or ylim[[2]] <- c(1, 50)
plot(ans6, screens = screens, ylim = ylim)
```
Arguments

file
character string or strings giving the name of the file(s) which the data are to be read from/written to. See *read.table* and *write.table* for more information. Alternatively, in *read.zoo*, file can be a connection or a data.frame (e.g., resulting from a previous *read.table* call) that is subsequently processed to a "zoo" series.

format
date format argument passed to FUN.

tz
time zone argument passed to *as.POSIXct*.

FUN
a function for computing the index from the first column of the data. See details.

regular
logical. Should the series be coerced to class "zooreg" (if the series is regular)?

index.column
numeric vector or list. The column names or numbers of the data frame in which the index/time is stored. If the *read.table* colClasses argument is used and "NULL" is among its components then index.column refers to the column numbers after the columns corresponding to "NULL" in colClasses have been removed. If specified as a list then one argument will be passed to argument FUN per component so that, for example, index.column = list(1, 2) will cause FUN(x[,1], x[,2], ...) to be called whereas index.column = list(1:2) will cause FUN(x[,1:2], ...) to be called where x is a data frame of characters data. Here ... refers to format and/or tz, if they specified as arguments. index.column = 0 can be used to specify that the row names be used as the index. In the case that no row names were input sequential numbering is used. If index.column is specified as an ordinary vector then if it has the same length as the number of arguments of FUN (or FUN2 in the event that FUN2 is specified and FUN is not) then index.column is converted to a list. Also it is always converted to a list if it has length 1.

drop
logical. If the data frame contains just a single data column, should the second dimension be dropped?

x
a "zoo" object.

index.name
character with name of the index column in the written data file.

row.names
logical. Should row names be written? Default is FALSE because the row names are just character representations of the index.

col.names
logical. Should column names be written? Default is to write column names only if x has column names.

FUN2
function. It is applied to the time index after FUN and before aggregate. If FUN is not specified but FUN2 is specified then only FUN2 is applied.

split
NULL or column number or name or vector of numbers or names. If not NULL then the data is assumed to be in long format and is split according to the indicated columns. See the *R reshape* command for description of long data. If split = Inf then the first of each run among the times are made into a separate series, the second of each run and so on. If split= -Inf then the last of each run is made into a separate series, the second last and so on.

aggregate
logical or function. If set to TRUE, then *aggregate.zoo* is applied to the zoo object created to compute the mean of all values with the same time index. Alternatively, aggregate can be set to any other function that should be used for
aggregation. If FALSE (the default), no aggregation is performed and a warning is given if there are any duplicated time indexes. Note that most zoo functions do not accept objects with duplicate time indexes. See aggregate.zoo.

... further arguments passed to read.table or write.table, respectively.

text character. If file is not supplied and this is, then data are read from the value of text via a text connection. See below for an example.

Details

read.zoo is a convenience function which should make it easier to read data from a text file and turn it into a "zoo" series immediately. read.zoo reads the data file via read.table(file, ...). The column index.column (by default the first) of the resulting data is interpreted to be the index/time, the remaining columns the corresponding data. (If the file only has only column then that is assumed to be the data column and 1, 2, ... are used for the index.) To assign the appropriate class to the index, FUN can be specified and is applied to the first column.

To process the index, read.zoo calls FUN with the index as the first argument. If FUN is not specified, the following default is employed:

(a) If file is a data frame with a single index column that appears to be a time index already, then FUN = identity is used. The conditions for a readily produced time index are: It is not character or factor (and the arguments tz and format must not be specified).

(b) If the conditions from (a) do not hold then the following strategy is used. If there are multiple index columns they are pasted together with a space between each. Using the (pasted) index column:

(1) If tz is specified then the index column is converted to POSIXct. (2) If format is specified then the index column is converted to Date. (3) Otherwise, a heuristic attempts to decide between "numeric", "POSIXct", and "Date" by trying them in that order (which may not always succeed though). By default, only the standard date/time format is used. Hence, supplying format and/or tz is necessary if some date/time format is used that is not the default. And even if the default format is appropriate for the index, explicitly supplying FUN or at least format and/or tz typically leads to more reliable results than the heuristic.

If regular is set to TRUE and the resulting series has an underlying regularity, it is coerced to a "zooreg" series.

To employ other functions than read.table to read the initial data, further convenience interfaces read.csv.zoo etc. are provided.

write.zoo is a convenience function for writing "zoo" series to text files. It first coerces its argument to a "data.frame", adds a column with the index and then calls write.table.

See also vignette("zoo-read", package = "zoo") for detailed examples.

Value

read.zoo returns an object of class "zoo" (or "zooreg").

Note

read.zoo works by first reading the data in using read.table and then processing it. This implies that if the index field is entirely numeric the default is to pass it to FUN or the built-in date conversion routine a number, rather than a character string. Thus, a date field such as 09122007 intended to
represent December 12, 2007 would be seen as 9122007 and interpreted as the 91st day thereby generating an error.

This comment also applies to trailing decimals so that if 2000.10 were intended to represent the 10th month of 2000 in fact it would receive 2000.1 and regard it as the first month of 2000 unless similar precautions were taken.

In the above cases the index field should be specified to be "character" so that leading or trailing zeros are not dropped. This can be done by specifying a "character" index column in the "colClasses" argument, which is passed to read.table, as shown in the examples below.

Examples

## this manual page provides a few typical examples, many more cases
## are covered in vignette("zoo-read", package = "zoo")

## read text lines with a single date column
Lines <- "2013-12-24 2
2013-12-25 3
2013-12-26 8"
read.zoo(text = Lines, FUN = as.Date) # explicit coercion
read.zoo(text = Lines, format = "%Y-%m-%d") # same
read.zoo(text = Lines) # same, via heuristic

## read text lines with date/time in separate columns
2013-12-25 12:41:22.25 3
2013-12-26 12:41:22.75 8"
read.zoo(text = Lines, index = 1:2,
FUN = paste, FUN2 = as.POSIXct) # explicit coercion
read.zoo(text = Lines, index = 1:2, tz = "") # same
read.zoo(text = Lines, index = 1:2) # same, via heuristic

## read directly from a data.frame (artificial and built-in BOD)
dat <- data.frame(date = paste("2000-01-", 10:15, sep = ",
    a = sin(1:6), b = cos(1:6))
read.zoo(dat)
data("BOD", package = "datasets")
read.zoo(BOD)

## Not run:
## descriptions of typical examples

## turn *numeric* first column into yearmon index
## where number is year + fraction of year represented by month
z <- read.zoo("foo.csv", sep = ",", FUN = as.yearmon)

## first column is of form yyyy.mm
## (Here we use format in place of as.character so that final zero
CC is not dropped in dates like 2001.10 which as.character would do.)
f <- function(x) as.yearmon(format(x, nsmall = 2), "%Y.%m")
z <- read.zoo("foo.csv", header = TRUE, FUN = f)

## turn *character* first column into "Date" index
## Assume lines look like: 12/22/2007 1.2
z <- read.zoo("foo.tab", format = "%m/%d/%Y")

# Suppose lines look like: 09/12/2007 1.2 and there is no header
z <- read.zoo("foo.txt", format = "%d%m%Y")

## csv file with first column of form YYYY-mm-dd HH:MM:SS
## Read in times as "chron" class. Requires chron 2.3-22 or later.
z <- read.zoo("foo.csv", header = TRUE, sep = ",", FUN = as.chron)

## same but with custom format. Note as.chron uses POSIXt-style
## Read in times as "chron" class. Requires chron 2.3-24 or later.
z <- read.zoo("foo.csv", header = TRUE, sep = ",", FUN = as.chron, format = "")

## same file format but read it in times as "POSIXct" class.
z <- read.zoo("foo.csv", header = TRUE, sep = ",", tz = ")

## csv file with first column mm-dd-yyyy. Read times as "Date" class.
z <- read.zoo("foo.csv", header = TRUE, sep = ",", format = "%m-%d-%Y")

## whitespace separated file with first column of form YYYY-mm-ddTHH:MM:SS
## and no headers. T appears literally. Requires chron 2.3-22 or later.
z <- read.zoo("foo.csv", FUN = as.chron)

# read in all csv files in the current directory and merge them
read.zoo(Sys.glob("*.csv"), header = TRUE, sep = ",")

# We use "NULL" in colClasses for those columns we don't need but in
# col.names we still have to include dummy names for them. Of what
# is left the index is the first three columns (1:3) which we convert
# to chron class times in FUN and then truncate to 5 seconds in FUN2.
# Finally we use aggregate = mean to average over the 5 second intervals.
library("chron")

---

rollapply Apply Rolling Functions

Description

A generic function for applying a function to rolling margins of an array.

Usage

```r
rollapply(data, ...)  # S3 method for class 'ts'
rollapply(data, ...)  # S3 method for class 'zoo'
rollapply(data, width, FUN, ..., by = 1, by.column = TRUE,
          fill = if (na.pad) NA, na.pad = FALSE, partial = FALSE,
          align = c("center", "left", "right"), coredata = TRUE)
## Default S3 method:
rollapply(data, ...)
rollapplyr(..., align = "right")
```

Arguments

data the data to be used (representing a series of observations).

width numeric vector or list. In the simplest case this is an integer specifying the window width (in numbers of observations) which is aligned to the original sample according to the align argument. Alternatively, width can be a list regarded as offsets compared to the current time, see below for details.

FUN the function to be applied.

... optional arguments to FUN.

by calculate FUN at every by-th time point rather than every point. by is only used if width is length 1 and either a plain scalar or a list.

by.column logical. If TRUE, FUN is applied to each column separately.

fill a three-component vector or list (recycled otherwise) providing filling values at the left/within/to the right of the data range. See the fill argument of `na.fill` for details.

na.pad deprecated. Use fill = NA instead of na.pad = TRUE.
partial logical or numeric. If FALSE (default) then FUN is only applied when all indexes of the rolling window are within the observed time range. If TRUE, then the subset of indexes that are in range are passed to FUN. A numeric argument to partial can be used to determine the minimal window size for partial computations. See below for more details.

align specifies whether the index of the result should be left- or right-aligned or centered (default) compared to the rolling window of observations. This argument is only used if width represents widths.

coredata logical. Should only the coredata(data) be passed to every width window? If set to FALSE the full zoo series is used.

Details

If width is a plain numeric vector its elements are regarded as widths to be interpreted in conjunction with align whereas if width is a list its components are regarded as offsets. In the above cases if the length of width is 1 then width is recycled for every by-th point. If width is a list its components represent integer offsets such that the i-th component of the list refers to time points at positions i + width[[i]]. If any of these points are below 1 or above the length of index(data) then FUN is not evaluated for that point unless partial = TRUE and in that case only the valid points are passed.

The rolling function can also be applied to partial windows by setting partial = TRUE. For example, if width = 3, align = "right" then for the first point just that point is passed to FUN since the two points to its left are out of range. For the same example, if partial = FALSE then FUN is not invoked at all for the first two points. If partial is a numeric then it specifies the minimum number of offsets that must be within range. Negative partial is interpreted as FALSE.

If FUN is mean, max or median and by.column is TRUE and width is a plain scalar and there are no other arguments then special purpose code is used to enhance performance. Also in the case of mean such special purpose code is only invoked if the data argument has no NA values. See rollmean, rollmax and rollmedian for more details.

Currently, there are methods for "zoo" and "ts" series and "default" method for ordinary vectors and matrices.

rollapplyr is a wrapper around rollapply that uses a default of align = "right".

Value

A object of the same class as data with the results of the rolling function.

Rolling Means/Maximums/Medians/Sums

**Description**

Generic functions for computing rolling means, maximums, medians, and sums of ordered observations.

**Usage**

```r
rollmean(x, k, fill = if (na.pad) NA, na.pad = FALSE, align = c("center", "left", "right"), ...)
rollmax(x, k, fill = if (na.pad) NA, na.pad = FALSE, align = c("center", "left", "right"), ...)
rollmedian(x, k, fill = if (na.pad) NA, na.pad = FALSE, align = c("center", "left", "right"), ...)
rollsum(x, k, fill = if (na.pad) NA, na.pad = FALSE, align = c("center", "left", "right"), ...)
```

```r
rollmeanr(..., align = "right")
rollmaxr(..., align = "right")
rollmedianr(..., align = "right")
rollsumr(..., align = "right")
```

**Arguments**

- **x**: an object (representing a series of observations).
- **k**: integer width of the rolling window. Must be odd for `rollmedian`.
- **fill**: a three-component vector or list (recycled otherwise) providing filling values at the left/within/to the right of the data range. See the `fill` argument of `na.fill` for details.
- **na.pad**: deprecated. Use `fill = NA` instead of `na.pad = TRUE`.
- **align**: character specifying whether the index of the result should be left- or right-aligned or centered (default) compared to the rolling window of observations.
- **...**: Further arguments passed to methods.
Details

These functions compute rolling means, maximums, medians, and sums respectively and are thus similar to `rollapply` but are optimized for speed.

Currently, there are methods for "zoo" and "ts" series and default methods. The default method of `rollmedian` is an interface to `runmed`. The default methods of `rollmean` and `rollsum` do not handle inputs that contain NAs. In such cases, use `rollapply` instead.

Value

An object of the same class as `x` with the rolling mean/max/median/sum.

See Also

`rollapply`, `zoo`, `na.fill`

Examples

```r
x.Date <- as.Date(paste(2004, rep(1:4, 4:1), sample(1:28, 10), sep = "-"))
x <- zoo(rnorm(12), x.Date)

rollmean(x, 3)
rollmax(x, 3)
rollmedian(x, 3)
rollsum(x, 3)

xm <- zoo(matrix(1:12, 4, 3), x.Date[1:4])
rollmean(xm, 3)
rollmax(xm, 3)
rollmedian(xm, 3)
rollsum(xm, 3)

rollapply(xm, 3, mean) # uses rollmean
rollapply(xm, 3, function(x) mean(x)) # does not use rollmean
```

window.zoo  Extract/Replacing the Time Windows of Objects

Description

Methods for extracting time windows of "zoo" objects and replacing it.

Usage

```r
## S3 method for class 'zoo'
window(x, index. = index(x), start = NULL, end = NULL, ...)
## S3 replacement method for class 'zoo'
window(x, index. = index(x), start = NULL, end = NULL, ...) <- value
```
Arguments

- **x**: an object.
- **index**: the index/time window which should be extracted.
- **start**: an index/time value. Only the indexes in `index` which are greater or equal to `start` are used. If the index class supports comparisons to character variables, as does "Date" class, "yearmon" class, "yearqtr" class and the chron package classes "dates" and "times" then `start` may alternately be a character variable.
- **end**: an index/time value. Only the indexes in `index` which are lower or equal to `end` are used. Similar comments about character variables mentioned under `start` apply here too.
- **value**: a suitable value object for use with `window(x)`.
- **...**: currently not used.

Value

Either the time window of the object is extracted (and hence return a "zoo" object) or it is replaced.

See Also

- **zoo**

Examples

```r
## zoo example
x.date <- as.Date(paste(2003, rep(1:4, 4:1), seq(1,19,2), sep = "-"))
x <- zoo(matrix(rnorm(20), ncol = 2), x.date)
x

window(x, start = as.Date("2003-02-01"), end = as.Date("2003-03-01"))
window(x, index = x.date[1:6], start = as.Date("2003-02-01"))
window(x, index = x.date[c(4, 8, 10)])[, 1:2] <- matrix(rnorm(20))
x

## for classes that support comparisons with "character" variables
## start and end may be "character"
window(x, start = "2003-02-01")

## zooreg example (with plain numeric index)
z <- zooreg(rnorm(10), start = 2000, freq = 4)
window(z, start = 2001.75)
window(z, start = c(2001, 4))

## replace data at times of d0 which are in dn
d1 <- d0 <- zoo(c(1:10) + 100
dn <- head(d0, 4)

window(d1, time(dn)) <- coredata(dn)
```
Description

Plot contiguous blocks along x axis. A typical use would be to highlight events or periods of missing data.

Usage

xblocks(x, ...)

## Default S3 method:
xblocks(x, y, ..., col = NULL, border = NA,
ybottom = par("usr")[3], ytop = ybottom + height,
height = diff(par("usr")[3:4]),
last.step = median(diff(tail(x))))

## S3 method for class 'zoo'
xblocks(x, y = x, ...)

## S3 method for class 'ts'
xblocks(x, y = x, ...)

Arguments

x, y
In the default method, x gives the ordinates along the x axis and must be in increasing order. y gives the color values to plot as contiguous blocks. If y is numeric, data coverage is plotted, by converting it into a logical (!is.na(y)). Finally, if y is a function, it is applied to x (time(x) in the time series methods). If y has character (or factor) values, these are interpreted as colors – and should therefore be color names or hex codes. Missing values in y are not plotted. The default color is taken from palette()[1]. If col is given, this over-rides the block colors given as y.
The ts and zoo methods plot the coredata(y) values against the time index index(x).

... In the default method, further arguments are graphical parameters passed on to gpar.

col
if col is specified, it determines the colors of the blocks defined by y. If multiple colors are specified they will be repeated to cover the total number of blocks.

border
border color.

ybottom, ytop, height
y axis position of the blocks. The default it to fill the whole plot region, but by setting these values one can draw blocks along the top of bottom of the plot. Note that height is not used directly, it only sets the default value of ytop.

last.step width (in native units) of the final block. Defaults to the median of the last 5 time steps (assuming steps are regular).
Details

Blocks are drawn forward in "time" from the specified x locations, up until the following value. Contiguous blocks are calculated using \texttt{rle}.

Examples

```r
## example time series:
set.seed(0)
flow <- ts(filter(rlnorm(200, mean = 1), 0.8, method = "r"))

## highlight values above and below thresholds.
## this draws on top using semi-transparent colors.
grb <- hcl(c(0, 0, 260), c = c(100, 0, 100), l = c(50, 90, 50), alpha = 0.3)
plot(flow)
xblocks(flow > 30, col = rgb[1]) ## high values red
xblocks(flow < 15, col = rgb[3]) ## low value blue
xblocks(flow >= 15 & flow <= 30, col = rgb[2]) ## the rest gray

## same thing:
plot(flow)
xblocks(time(flow), cut(flow, c(0,15,30,Inf), labels = rev(rgb)))

## another approach is to plot blocks underneath without transparency.
plot(flow)
## note that 'ifelse' keeps its result as class 'ts'
xblocks(ifelse(flow < mean(flow), hcl(0, 0, 90), hcl(0, 80, 70)))
## need to redraw data series on top:
lines(flow)
box()

## for single series only: plot.default has a panel.first argument
plot(time(flow), flow, type = "l",
     panel.first = xblocks(flow > 20, col = "lightgray"))
## (see also the 'panel' argument for use with multiple series, below)

## insert some missing values
flow[c(1:10, 50:80, 100)] <- NA

## the default plot shows data coverage
## (most useful when displaying multiple series, see below)
plot(flow)
xblocks(flow)

## can also show gaps:
```

plot(flow, type = "s")
xblocks(time(flow), is.na(flow), col = "gray")

## Example of alternating colors, here showing calendar months
flowdates <- as.Date("2000-01-01") + as.numeric(time(flow))
flowz <- zoo(coredata(flow), flowdates)
plot(flowz)
xblocks(flowz, months, ## i.e. months(time(flowz)),
       col = gray.colors(2, start = 0.7), border = "slategray")
lines(flowz)

## Example of multiple series.
## set up example data
z <- ts(cbind(A = 0:5, B = c(6:7, NA, NA, 10:11), C = c(NA, 13:17)))

## show data coverage only (highlighting gaps)
plot(z, panel = function(x, ...)
       xblocks(x, col = "darkgray"))

## draw gaps in darkgray
plot(z, type = "s", panel = function(x, ...)
       xblocks(time(x), is.na(x), col = "darkgray")
       lines(x, ...); points(x))

## Example of overlaying blocks from a different series.
## Are US presidential approval ratings linked to sunspot activity?
## Set block height to plot blocks along the bottom.
plot(presidents)
xblocks(sunspot.year > 50, height = 2)

---

**xyplot.zoo**

**Plot zoo Series with Lattice**

**Description**

xyplot methods for time series objects (of class "zoo", "its", or "tis").

**Usage**

## S3 method for class 'zoo'
xyplot(x, data, ...)

## S3 method for class 'zoo'
llines(x, y = NULL, ...)

## S3 method for class 'zoo'
lpolygons(x, y = NULL, ...)

## S3 method for class 'zoo'
lpoints(x, y = NULL, ...)

## S3 method for class 'zoo'
ltext(x, y = NULL, ...)
Arguments

- \(x, x0, x1\) time series object of class "zoo", "its" or "tis". For `panel.plot.default` it should be a numeric vector.
- \(y\) numeric vector or matrix.
- `data` not used.
- `...` arguments are passed to `xyplot.ts`, and may be passed through to `xyplot` and `panel.xyplot`.

Some of the commonly used arguments are:

- `screens` factor (or coerced to factor) whose levels specify which graph each series is to be plotted in. `screens = c(1, 2, 1)` would plot series 1, 2 and 3 in graphs 1, 2 and 1. This also defines the strip text in multi-panel plots.
- `scales` the default is set so that all series have the "same" X axis but "free" Y axis. See `xyplot` in the `lattice` package for more information on scales.
- `layout` numeric vector of length 2 specifying number of columns and rows in the plot, see `xyplot` for more details. The default is to fill columns with up to 6 rows.
- `xlab` character string used as the X axis label.
- `ylab` character string used as the Y axis label. If there are multiple panels it may be a character vector the same length as the number of panels, but \(\text{NOTE}\) in this case the vector should be reversed OR the argument `as.table` set to `FALSE`.
- `lty`, `lwd`, `pch`, `type`, `col` graphical arguments passed to `panel.xyplot`. These arguments can also be vectors or (named) lists, see details for more information.

Details

`xyplot.zoo` plots a "zoo", "its" or "tis" object using `xyplot.ts` from `lattice`. Series of other classes are coerced to "zoo" first.

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1,2), c(3,4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way.

\(\text{NOTE}\) that since `zoo` 1.6-3 `plot.panel.default` and `plot.panel.custom` are no longer necessary, as normal panel functions (`panel.xyplot` by default) will work.

Similarly, there are now methods for the generic `lattice` drawing functions `llines`, `lpoints`, and `ltext`. These can also be called as `panel.lines`, `panel.points`, and `panel.text`, respectively. The old interfaces (`panel.lines.zoo`, `panel.points.zoo`, and `panel.text.zoo`), will be removed in future versions. `panel.polygon.zoo` may also be removed.
Value

Invisibly returns a "trellis" class object. Printing this object using print will display it.

See Also

`xyplot.ts`, `zoo`, `plot.ts`, `barplot`, `plot.zoo`

Examples

```r
if(require("lattice") & require("grid")) {
  set.seed(1)
  z <- zoo(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))

  # plot z using same Y axis on all plots
  xyplot(z, scales = list(y = list(relation = "same", alternating = FALSE)))

  # plot a double-line-width running mean on the panel of b.
  # Also add a grid.
  # We show two ways to do it.

  # change strip background to levels of grey
  # If you like the defaults, this can be omitted.
  strip.background <- trellis.par.get("strip.background")
  trellis.par.set(strip.background = list(col = grey(7/18)))

  # Number 1. Using trellis.focus.
  print( xypplot(z ) )
  trellis.focus("panel", 1, 2, highlight = FALSE)
  # (or just trellis.focus() for interactive use)
  z.mean <- rollmean(z, 3)
  panel.lines(z.mean[,2], lwd = 2)
  panel.grid(h = 10, v = 10, col = "grey", lty = 3)
  trellis.unfocus()

  # Number 2. Using a custom panel routine.
  xypplot(z, panel = function(x, y, ...) {
    if (packet.number() == 2) {
      panel.grid(h = 10, v = 10, col = "grey", lty = 3)
      panel.lines(rollmean(zoo(y, x), 3), lwd = 2)
    }
    panel.xyplot(x, y, ...)
  })

  # plot a light grey rectangle "behind" panel b
  trellis.focus("panel", 1, 2)
  grid.rect(x = 2, w = 1, default.units = "native",
            gp = gpar(fill = "light grey")
  # do.call("panel xyplot", trellis.panelArgs())
  do.call("panel.lines", trellis.panelArgs()[1:2])
  trellis.unfocus()
}
```
# a better method is to use a custom panel function.
# see also panel.xblocks() and layer() in the latticeExtra package.

# same but make first panel twice as large as others
lopt <- list(layout.heights = list(panel = list(x = c(2,1,1))))
xyplot(z, lattice.options = lopt)
# add a grid
update(trellis.last.object(), type = c("l", "g"))

# Plot all in one panel.
xyplot(z, screens = 1)
# Same with default styles and auto.key:
xyplot(z, superpose = TRUE)

# Plot first two columns in first panel and third column in second panel.
# Plot first series using points, second series using lines and third
# series via overprinting both lines and points
# Use colors 1, 2 and 3 for the three series (1=black, 2=red, 3=green)
# Make 2nd (lower) panel 3x the height of the 1st (upper) panel
# Also make the strip background orange.
p <- xyplot(z, screens = c(1,1,2), type = c("p", "l", "o"), col = 1:3,
  par.settings = list(strip.background = list(col = "orange")))
print(p, panel.height = list(y = c(1, 3), units = "null"))

# Example of using a custom axis
# Months are labelled with smaller ticks for weeks and even smaller
# ticks for days.
Days <- seq(from = as.Date("2006-1-1"), to = as.Date("2006-8-8"), by = "day")

ids <- playGetIDs()
z3[ids,]

## another example of using playwith with zoo
# set up data
dat <- zoo(matrix(rnorm(100*100), ncol=100), Sys.Date()+1:100)
colnames(dat) <- paste("Series", 1:100)

# This will give you a spin button to choose the column to plot,
# and a button to print out the current series number.
playwith(xyplot(dat[,c(1,i)]), parameters = list(i = 1:100,
          do_something = function(playState) print(playState$env$i))

## End(Not run)

yearmon

An Index Class for Monthly Data

Description

"yearmon" is a class for representing monthly data.

Usage

yearmon(x)
Arguments

- **x**: numeric (interpreted as being “in years”).

Details

The "yearmon" class is used to represent monthly data. Internally it holds the data as year plus 0 for January, 1/12 for February, 2/12 for March and so on in order that its internal representation is the same as ts class with frequency = 12. If x is not in this format it is rounded via floor(12*x + .0001)/12.

There are coercion methods available for various classes including: default coercion to "yearmon" (which coerces to "numeric" first) and coercions to and from "yearmon" to "Date" (see below), "POSIXct", "POSIXlt", "numeric", "character" and "jul". The last one is from the "tis" package available on CRAN. In the case of as.yearmon.POSIXt the conversion is with respect to GMT. (Use as.yearmon(format(...)) for othertime zones.) In the case of as.yearmon.character the format argument uses the same percent code as "Date". These are described in strptime. Unlike "Date" one can specify a year and month with no day. Default formats of "%Y-%m", "%Y-%m-%d" and "%b %Y".

There is an is.numeric method which returns FALSE.

as.Date.yearmon and as.yearmon.yearqtr each has an optional second argument of "frac" which is a number between 0 and 1 inclusive that indicates the fraction of the way through the period that the result represents. The default is 0 which means the beginning of the period.

There is also a date method for as.yearmon usable with objects created with package date.

Sys.yearmon() returns the current year/month and methods for min, max and range are defined (by defining a method for Summary).

A yearmon mean method is also defined.

Value

Returns its argument converted to class yearmon.

See Also

- yearqtr, zoo, zooreg, ts

Examples

```r
x <- as.yearmon(2000 + seq(0, 23)/12)
x

as.yearmon("mar07", "%b%y")
as.yearmon("2007-03-01")
as.yearmon("2007-12")

# returned Date is the fraction of the way through
# the period given by frac (= 0 by default)
as.Date(x)
as.Date(x, frac = 1)
as.POSIXct(x)
```
Given a Date, x, return the Date of the next Friday:
```
nextfri <- function(x) 7 * ceiling(as.numeric(x - 1)/7) + as.Date(1)
```

Given a Date, d, return the same Date in the following month:
```
next.month <- function(d) as.Date(as.yearmon(d) + 1/12) + as.numeric(d - as.Date(as.yearmon(d)))
```

3rd Friday in last month of the quarter of Date x:
```
as.Date(as.yearmon(as.yearqtr(x)) + 2/12) + 14
```

```
z <- zoo(rnorm(24), x, frequency = 12)
z
```

```
## convert data fram to multivariate monthly "ts" series
## 1. read raw data
Lines.raw <- read.table("ID Date Count
123 20 May 1999 1
123 21 May 1999 3
222 1 Feb 2000 2
222 3 Feb 2000 4
")

DF <- read.table(textConnection(Lines.raw), skip = 1,
col.names = c("ID", "d", "b", "Y", "Count"))

## 2. fix raw date
DF$yearmon <- as.yearmon(paste(DF$b, DF$Y), "%b %Y")

## 3. aggregate counts over months, convert to zoo and merge over IDs
ag <- function(DF) aggregate(zoo(DF$Count), DF$yearmon, sum)
z <- do.call("merge.zoo", lapply(split(DF, DF$ID), ag))

## 4. convert to "zooreg" and then to "ts"
frequency(z) <- 12
as.ts(z)

xx <- zoo(seq_along(x), x)

## aggregating over year
as.year <- function(x) as.numeric(floor(as.yearmon(x)))
aggregate(xx, as.year, mean)

### yearqtr

An Index Class for Quarterly Data

**Description**

"yearqtr" is a class for representing quarterly data.
Usage

```r
yearqtr(x)
as.yearqtr(x, ...)
## S3 method for class 'character'
as.yearqtr(x, format, ...)
## S3 method for class 'yearqtr'
format(x, format = "%Y Q%q", ...)
```

Arguments

- `x`: for `yearqtr` a numeric (interpreted as being “in years”). For `as.yearqtr` another date class object. For the "yearqtr" method of format an object of class "yearqtr" or if called as `format.yearqtr` then an object with an `as.yearqtr` method that can be coerced to "yearqtr".
- `format`: character string specifying format. For coercing to "yearqtr" from character: "%Y" and "%q" have to be specified. For formatting an existing "yearqtr": "%C", "%Y", "%y" and "%q", if present, are replaced with the century, year, last two digits of the year, and quarter (i.e. a number between 1 and 4), respectively.
- `...`: arguments passed ot other methods.

Details

The "yearqtr" class is used to represent quarterly data. Internally it holds the data as year plus 0 for Quarter 1, 1/4 for Quarter 2 and so on in order that its internal representation is the same as `ts` class with frequency = 4. If `x` is not in this format it is rounded via `floor((4*x + .0001))/4`. `as.yearqtr.character` uses a default format of "%Y %q", "%Y q%q" or "%Y-%q" according to whichever matches. `%q` accepts the numbers 1-4 (possibly with leading zeros).

There are coercion methods available for various classes including: default coercion to "yearqtr" (which coerces to "numeric" first) and coercion from "yearqtr" to "Date" (see below), "POSIXct", "POSIXlt", "numeric", "character" and "jul". The last one is from the frame package on CRAN.

There is an `is.numeric` method which returns `FALSE`.

There is also a date method for `as.yearqtr` usable with objects created with package `date`.

`Sys.yearqtr()` returns the current year/month and methods for `min`, `max` and `range` are defined (by defining a method for `Summary`).

A `yearqtr` `mean` method is also defined.

Certain methods support a `frac` argument. See `yearmon`.

Value

`yearqtr` and `as.yearqtr` return the first argument converted to class `yearqtr`. The `format` method returns a character string representation of its argument first argument.

See Also

`yearmon`, `zoo`, `zooreg`, `ts`, `strptime`. 
Examples

```r
x <- as.yearqtr(2000 + seq(0, 7)/4)
x

format(x, "%Y Quarter %q")
as.yearqtr("2001 Q2")
as.yearqtr("2001 q2") # same
as.yearqtr("2001-2") # same

# returned Date is the fraction of the way through
# the period given by frac (= 0 by default)
dd <- as.Date(x)
format.yearqtr(dd)
as.Date(x, frac = 1)
as.POSIXct(x)

zz <- zoo(rnorm(8), x, frequency = 4)
zz
as.ts(zz)
```

zoo

Z's Ordered Observations

Description

zoo is the creator for an S3 class of indexed totally ordered observations which includes irregular
time series.

Usage

```r
zoo(x = NULL, order.by = index(x), frequency = NULL,
calendar = getOption("zoo.calendar", TRUE))
## S3 method for class 'zoo'
print(x, style = , quote = FALSE, ...)
```

Arguments

- **x**: a numeric vector, matrix or a factor.
- **order.by**: an index vector with unique entries by which the observations in x are ordered. See the details for support of non-unique indexes.
- **frequency**: numeric indicating frequency of order.by. If specified, it is checked whether order.by and frequency comply. If so, a regular "zoo" series is returned, i.e., an object of class c("zooreg", "zoo"). See below and zooreg for more details.
- **calendar**: logical. If frequency is specified and is 4 or 12: Should yearqtr or yearmon be used for a numeric index order.by?
style a string specifying the printing style which can be "horizontal" (the default for vectors), "vertical" (the default for matrices) or "plain" (which first prints the data and then the index).

quote logical. Should characters be quoted?

... further arguments passed to the print methods of the data and the index.

Details

zoo provides infrastructure for ordered observations which are stored internally in a vector or matrix with an index attribute (of arbitrary class, see below). The index must have the same length as NROW(x) except in the case of a zero length numeric vector in which case the index length can be any length. Emphasis has been given to make all methods independent of the index/time class (given in order.by). In principle, the data x could also be arbitrary, but currently there is only support for vectors and matrices and partial support for factors.

zoo is particularly aimed at irregular time series of numeric vectors/matrices, but it also supports regular time series (i.e., series with a certain frequency). zoo’s key design goals are independence of a particular index/date/time class and consistency with ts and base R by providing methods to standard generics. Therefore, standard functions can be used to work with "zoo" objects and memorization of new commands is reduced.

When creating a "zoo" object with the function zoo, the vector of indexes order.by can be of (a single) arbitrary class (if x is shorter or longer than order.by it is expanded accordingly), but it is essential that ORDER(order.by) works. For other functions it is assumed that c(), length(), MATCH() and subsetting [, work. If this is not the case for a particular index/date/time class, then methods for these generic functions should be created by the user. Note, that to achieve this, new generic functions ORDER and MATCH are created in the zoo package with default methods corresponding to the non-generic base functions order and match. Note that the order and hence the default ORDER typically work if there is a xtfrm method. Furthermore, for certain (but not for all) operations the index class should have an as.numeric method (in particular for regular series) and an as.character method might improve printed output (see also below).

The index observations order.by should typically be unique, such that the observations can be totally ordered. Nevertheless, zoo() is able to create "zoo" objects with duplicated indexes (with a warning) and simple methods such as plot() or summary() will typically work for such objects. However, this is not formally supported as the bulk of functionality provided in zoo requires unique index observations/time stamps. See below for an example how to remove duplicated indexes.

If a frequency is specified when creating a series via zoo, the object returned is actually of class "zooreg" which inherits from "zoo". This is a subclass of "zoo" which relies on having a "zoo" series with an additional "frequency" attribute (which has to comply with the index of that series). Regular "zooreg" series can also be created by zooreg, the zoo analogue of ts. See the respective help page and is.regular for further details.

Methods to standard generics for "zoo" objects currently include: print (see above), summary, str, head, tail, [ (subsetting), rbind, cbind, merge (see merge.zoo), aggregate (see aggregate.zoo), rev, split (see aggregate.zoo), barplot, plot and lines (see plot.zoo). For multivariate "zoo" series with column names the $ extractor is available, behaving similar as for "data.frame" objects. Methods are also available for median and quantile.

ifelse.zoo is not a method (because ifelse is not a generic) but must be written out including the .zoo suffix.
To “prettify” printed output of "zoo" series the generic function index2char is used for turning index values into character values. It defaults to using as.character but can be customized if a different printed display should be used (although this should not be necessary, usually).

The subsetting method [ work essentially like the corresponding functions for vectors or matrices respectively, i.e., takes indexes of type "numeric", "integer" or "logical". But additionally, it can be used to index with observations from the index class of the series. If the index class of the series is one of the three classes above, the corresponding index has to be encapsulated in I() to enforce usage of the index class (see examples). Subscripting by a zoo object whose data contains logical values is undefined.

Additionally, zoo provides several generic functions and methods to work (a) on the data contained in a "zoo" object, (b) the index (or time) attribute associated to it, and (c) on both data and index:

(a) The data contained in "zoo" objects can be extracted by coredata (strips off all "zoo"-specific attributes) and modified using coredata<-. Both are new generic functions with methods for "zoo" objects, see coredata.

(b) The index associated with a "zoo" object can be extracted by index and modified by index<-. As the interpretation of the index as “time” in time series applications is more natural, there are also synonymous methods time and time<-. The start and the end of the index/time vector can be queried by start and end. See index.

(c) To work on both data and index/time, zoo provides methods lag, diff (see lag.zoo) and window, window<-. (see window.zoo).

In addition to standard group generic function (see Ops), the following mathematical operations are available as methods for "zoo" objects: transpose t which coerces to a matrix first, and cumsum, cumprod, cummin, cummax which are applied column wise.

Coercion to and from "zoo" objects is available for objects of various classes, in particular "ts", "irts" and "its" objects can be coerced to "zoo", the reverse is available for "its" and for "irts" (the latter in package tseries). Furthermore, "zoo" objects can be coerced to vectors, matrices and lists and data frames (dropping the index/time attribute). See as.zoo.

Several methods are available for NA handling in the data of "zoo" objects: na.aggregate which uses group means to fill in NA values, na.approx which uses linear interpolation to fill in NA values. na.contiguous which extracts the longest consecutive stretch of non-missing values in a "zoo" object, na.fill which uses fixed specified values to replace NA values, na.locf which replaces NAs by the last previous non-NA, na.omit which returns a "zoo" object with incomplete observations removed, na.spline which uses spline interpolation to fill in NA values and na.StructTS which uses a seasonal Kalman filter to fill in NA values, na.trim which trims runs of NAs off the beginning and end but not in the interior. Yet another NA routine can be found in the stinepack package where na.stinterp performs Stineman interpolation.

A typical task to be performed on ordered observations is to evaluate some function, e.g., computing the mean, in a window of observations that is moved over the full sample period. The generic function rollapply provides this functionality for arbitrary functions and more efficient versions rollmean, rollmax, rollmedian are available for the mean, maximum and median respectively.

The zoo package has an as.Date numeric method which is similar to the one in the core of R except that the origin argument defaults to January 1, 1970 (whereas the one in the core of R has no default).

Note that since zoo uses date/time classes from base R and other packages, it may inherit bugs or problems with those date/time classes. Currently, there is one such known problem with the c
method for the POSIXct class in base R: If x and y are POSIXct objects with tzone attributes, the attribute will always be dropped in c(x, y), even if it is the same across both x and y. Although this is documented at \code{c.POSIXct}, one may want to employ a workaround as shown at \url{https://stat.ethz.ch/pipermail/r-devel/2010-August/058112.html}.

Value

A vector or matrix with an "index" attribute of the same dimension (\code{NROW(x)}) by which x is ordered.

## x1[x1 > 3] is not officially supported since
## x1 > 3 is of class "zoo", not "logical".
## Use one of these instead:
x1[which(x1 > 3)]
x1[coredata(x1 > 3)]
x1[as.logical(x1 > 3)]
subset(x1, x1 > 3)

## any class supporting the methods discussed can be used
## as an index class. Here are examples using complex numbers

and letters as the time class.

```r
z4 <- zoo(11:15, complex(real = c(1, 3, 4, 5, 6), imag = c(0, 1, 0, 0, 1)))
merge(z4, lag(z4))

z5 <- zoo(11:15, letters[1:5])
merge(z5, lag(z5))
```

# index values relative to 2001Q1

```r
z6 <- zooReg(cbind(a = 1:10, b = 11:20), start = as.yearqtr(2000), freq = 4)
z6[] <- mapply("/", as.data.frame(z6), coredata(z6[as.yearqtr("2001Q1")]))
```

## even though time index must be unique zoo (and read.zoo)

## will both allow creation of such illegal objects with

## a warning (rather than an error) to give the user a

## chance to fix them up. Extracting and replacing times

## and aggregate.zoo will still work.

## Not run:

This gives a warning

and then creates an illegal zoo object

```r
z6 <- zoo(11:15, c(1, 1, 2, 2, 5))
z6
```

# fix it up by averaging duplicates

```r
aggregate(z6, identity, mean)
```

# or, fix it up by taking last in each set of duplicates

```r
aggregate(z6, identity, tail, 1)
```

# fix it up via interpolation of duplicate times

```r
time(z6) <- na.approx(1Felse(duplicated(time(z6)), NA, time(z6)), na.rm = FALSE)
```

# if there is a run of equal times at end they

# wind up as NAs and we cannot have NA times

```r
z6 <- z6[!is.na(time(z6))]
z6
```

x1 <- x1 <- zoo (matrix (1:12, nrow = 3), as.Date("2008-08-01") + 0:2)
colnames (x1) <- c ("A", "B", "C", "D")
x2 <- zoo (matrix (1:12, nrow = 3), as.Date("2008-08-01") + 1:3)
colnames (x2) <- c ("B", "C", "D", "E")

both.dates = as.Date (intersect (index (x1), index (x2)))
both.cols = intersect (colnames (x1), colnames (x2))

```r
x1[both.dates, both.cols]
```

## there is ".zoo" but no ":<.zoo" however four of the following

## five examples work

## wrong

## x1[both.dates, both.cols] <- x2[both.dates, both.cols]
zooreg

Description

zooreg is the creator for the S3 class "zooreg" for regular "zoo" series. It inherits from "zoo" and is the analogue to ts.

Usage

zooreg(data, start = 1, end = numeric(), frequency = 1,
       deltat = 1, ts.eps = getOption("ts.eps"), order.by = NULL,
       calendar = getOption("zoo.calendar", TRUE))

Arguments

data a numeric vector, matrix or a factor.
start the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit.
end the time of the last observation, specified in the same way as start.
frequency the number of observations per unit of time.
deltat the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of frequency or deltat should be provided.
ts.eps time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than ts.eps.
order.by  a vector by which the observations in x are ordered. If this is specified the arguments start and end are ignored and zoo(data, order.by, frequency) is called. See zoo for more information.

calendar  logical. Should yearqtr or yearmon be used for a numeric time index with frequency 4 or 12, respectively?

Details

Strictly regular series are those whose time points are equally spaced. Weakly regular series are strictly regular time series in which some of the points may have been removed but still have the original underlying frequency associated with them. "zooreg" is a subclass of "zoo" that is used to represent both weakly and strictly regular series. Internally, it is the same as "zoo" except it also has a "frequency" attribute. Its index class is more restricted than "zoo". The index: 1. must be numeric or a class which can be coerced via as.numeric (such as yearmon, yearqtr, Date, POSIXct, tis, xts, etc.). 2. when converted to numeric must be expressible as multiples of 1/frequency. 3. group generic functions Ops should be defined, i.e., adding/subtracting a numeric to/from the index class should produce the correct value of the index class again.

zooreg is the zoo analogue to ts. The arguments are almost identical, only in the case where order.by is specified, zoo is called with zoo(data, order.by, frequency). It creates a regular series of class "zooreg" which inherits from "zoo". It is essentially a "zoo" series with an additional "frequency" attribute. In the creation of "zooreg" objects (via zoo, zooreg, or coercion functions) it is always check whether the index specified complies with the frequency specified.

The class "zooreg" offers two advantages over code "ts": 1. The index does not have to be plain numeric (although that is the default), it just must be coercible to numeric, thus printing and plotting can be customized. 2. This class can not only represent strictly regular series, but also series with an underlying regularity, i.e., where some observations from a regular grid are omitted.

Hence, "zooreg" is a bridge between "ts" and "zoo" and can be employed to coerce back and forth between the two classes. The coercion function as.zoo.ts returns therefore an object of class "zooreg" inheriting from "zoo". Coercion between "zooreg" and "zoo" is also available and drops or tries to add a frequency respectively.

For checking whether a series is strictly regular or does have an underlying regularity the generic function is.regular can be used.

Methods to standard generics for regular series such as frequency, deltat and cycle are available for both "zooreg" and "zoo" objects. In the latter case, it is checked first (in a data-driven way) whether the series is in fact regular or not.

as.zooreg.tis has a class argument whose value represents the class of the index of the zooreg object into which the tis object is converted. The default value is "ti". Note that the frequency of the zooreg object will not necessarily be the same as the frequency of the tis object that it is converted from.

Value

An object of class "zooreg" which inherits from "zoo". It is essentially a "zoo" series with a "frequency" attribute.

zoo, is.regular

Examples

```r
## equivalent specifications of a quarterly series
## starting in the second quarter of 1959.
zooreg(1:10, frequency = 4, start = c(1959, 2))
as.zoo(ts(1:10, frequency = 4, start = c(1959, 2)))
zoo(1:10, seq(1959.25, 1961.5, by = 0.25), frequency = 4)

## use yearqtr class for indexing the same series
z <- zoo(1:10, yearqtr(seq(1959.25, 1961.5, by = 0.25)), frequency = 4)
z z[-(3:4)]

## create a regular series with a "Date" index
zooreg(1:5, start = as.Date("2000-01-01"))
## or with "yearmon" index
zooreg(1:5, end = yearmon(2000))

## lag and diff (as diff is defined in terms of lag)
## act differently on zoo and zooreg objects!
## lag.zoo moves a point to the adjacent time whereas
## lag.zooreg moves a point by deltat
x <- c(1, 2, 3, 6)
z <- zoo(x, x)
zr <- as.zooreg(zz)
lag(zz, k = -1)
lag(zr, k = -1)
diff(zz)
diff(zr)

## lag.zooreg wihtout and with na.pad
lag(zr, k = -1)
lag(zr, k = -1, na.pad = TRUE)

## standard methods available for regular series
frequency(z)
deltat(z)
cycle(z)
cycle(z[-(3:4)])

zz <- zoo(1:6, as.Date(c("1960-01-29", "1960-02-29", "1960-03-31",
# this converts zz to "zooreg" and then to "ts" expanding it to a daily
# series which is 154 elements long, most with NAs.
## Not run:
length(as.ts(zz)) # 154

## End(Not run)
# probably a monthly "ts" series rather than a daily one was wanted.
```
# This variation of the last line gives a result only 6 elements long.
length(as.ts(aggregate(zz, as.yearmon, c))) # 6

zzr <- as.zooreg(zz)

dl <- as.Date(c("2000-01-01", "2000-02-01", "2000-03-01", "2000-04-01"))
zrd <- as.zooreg(zoo(1:4, dd))
